Different scenarios involving varying levels of prospect, refuge, and escape offer an ideal opportunity for potential offenders to successfully commit a crime against their target. This same ideal set of circumstances is also the most likely to induce fear of crime among other site users. A site characterized by low or blocked prospect would be most likely to instill in site users a feeling of uncertainty and fear of crime. If the line of sight is restricted (e.g., by narrow corridors, many trees, or shrubs obscuring the view), area users are more likely to experience fear. Similarly, areas offering refuge or concealment for potential offenders (e.g., brick walls or large planters to hide behind) would be more likely to elicit a sense of fear in site users. Finally, sites lacking opportunities or avenues for victims to escape (e.g., dead ends) would be most likely to bring out feelings of fear among site users.

The combination of low prospect for the victim, high refuge for the potential offender, and few avenues of escape for the victim are those most likely to elicit fear and result in concentrations of fear at the proximate level.

Levels of Fear Spots

Fear spots exist at three levels of analysis: macro, meso, and micro. The macro-level concentration of fear occurs within nations or cities. For example, a country in a state of war would be perceived as unsafe and a fearful environment in which to find oneself. The meso level represents a narrower scale, such that an entire city may not be perceived as dangerous, but only certain parts or neighborhoods within that city. Finally, micro-level fear spots are site specific. That is, fear is concentrated within a specific site, area within a site, or situation. To date, only micro-level fear spots have been subject to empirical attention, and the research of Fisher and Nasar and others indicates that fear does indeed concentrate at the site level based on elements of prospect, refuge, and escape.

Fisher and Nasar's Hot Spots of Fear Research

Different constellations of aspects of the physical environment are known to generate fear of crime. Fisher and Nasar introduced the idea that fear of crime may be concentrated in sites that are characterized by varying degrees of prospect, refuge, and escape.

Fisher and Nasar designed a study to examine fear of crime in relation to physical site features on a college campus to understand more fully the role of these site features on fear of crime. Based on examinations of site features at and around Ohio State University by graduate students in landscape architecture, planning and design, observations of pedestrian site user (e.g., college student) behaviors, official campus crime data, and self-reported survey responses from site users, the researchers identified specific site features that resulted in concentrations of high levels of fear. The researchers reported that those areas most avoided were characterized by low prospect and high refuge. Areas considered low prospect, but offering only moderate refuge were avoided only after dark. In addition, student surveys indicated that females reported feeling significantly less safe than did males while

traveling at night. Pedestrians traveling in groups were more likely than those traveling alone to enter into the areas judged to be unsafe. The consistent findings related to site behavior based upon physical design are that areas that seem unsafe are avoided after dark, and that the combination of low prospect, lack of escape, and high refuge are most likely to affect behavior through feelings of fear.

Research on Site Characteristics as Predictors of Fear of Crime

Research subsequent to Fisher and Nasar's work has examined different types of environments characterized by varying degrees of prospect, refuge, and escape. Many of these studies have been conducted by showing study participants pictures or videos of different environments and asking them about their fear and perceived risk if they were actually in such an environment. Such studies have generally been supportive of the earlier conclusions that elements of prospect, refuge, and escape are important predictors of fear, hot spots of fear, and perceived risk of attack.

Research has also been conducted that considered the role of physical features in different types of environments (e.g., settings in nature, urban spaces such as alleyways). Findings from these studies indicated that feelings of tranquility are most related to settings in nature, and danger is associated with urban settings. Other examinations of urban settings (e.g., alleyways) have extended the site features of prospect, refuge, and escape identified by Fisher and Nasar to also consider the role of additional features such as entrapment, setting care, mystery, shadow, curvature, length, and the width of alleyways in provoking fear. Aspects of setting care are most related to feelings of preference, and shadow is the strongest predictor of feelings of danger. With respect to measurement, prospect and escape have been combined and measured as one single concept, and refuge has been further refined to include measures of dark spots and hiding places. The studies using refined measures of proximity, refuge, and escape have reported statistically significant relationships between these measures and fear of crime that is similar to those reported in earlier studies.

HUMAN TRAFFICKING

Human trafficking, also known as modern-day slavery or trafficking in persons, is a criminal act

and a violation of basic human rights (e.g., right to freedom, right to dignity, right to equal protection of the law) that affects every country in the world. Human trafficking is one of the few crimes that has been pursued from a victim's perspective, with a focus on prevention of trafficking, protection of victims, and prosecution of traffickers. This entry explores the definition of trafficking and related common misunderstandings, and includes an examination of the size, scope, and patterns of trafficking; sample profiles of traffickers and victims; and responses to human trafficking.

Definition

In December of 2000 in Palermo, Italy, the world came together on the issue of trafficking in persons, finalizing the drafting of the Protocol to Prevent, Suppress and Punish Trafficking in Persons, Especially Women and Children, supplementing the United Nations Convention against Transnational Organized Crime, commonly known as the Protocol. The Protocol entered into force in December 2003. It defines the crime of human trafficking using three components: the process of obtaining the victim (e.g., recruiting, transporting, transferring, receiving, harboring), the means (e.g., deceit, coercion, abduction, threat, fraud, deception, abuse of power), and the goal (e.g., violence/sexual abuse, pornography, forced labor, involuntary servitude, debt bondage, prostitution, slavery). It includes human trafficking both for sexual exploitation and for labor.

Since the meeting in Palermo, 117 countries have signed the Protocol, but many of them have not yet modified their legislation to incorporate the crime of human trafficking into their penal code or fully implemented the process. This is not an easy task. It takes time, money, and a political will to change. The Protocol was developed through a process of consensus that then must be modified to operate within the various criminal justice systems throughout the world. For example, the United States legislation mirrors the Protocol, except that the United States does not include trafficking in human organs as a crime of human trafficking. The lack of full implementation within any country poses a problem for prosecution of traffickers within that country, as well as a problem for cooperation between countries that have differing legislation.

While many countries have signed the Protocol, the level of understanding of human trafficking is

limited, resulting in several common misunderstandings. It is widely known that at least 75% of the law enforcement officials around the world are unable to accurately define human trafficking, and the ability to define it is even less common among the general population, who serve as the frontline observers of the phenomenon. Trafficking refers to the act of commerce but is often mistaken to mean the individual must be moved or transported. Because commerce can occur without movement, human trafficking can be domestic as well as transnational.

Another common misunderstanding involves the confusion of human trafficking with illegal migration, smuggling, or labor exploitation. Illegal migration occurs when an individual crosses a national border without the appropriate paperwork or visa. Smuggling is the transportation of willing participants by a third party across a national boundary without the appropriate paperwork. Labor exploitation is the act of obtaining labor without the appropriate remuneration.

The crime of trafficking may begin as smuggling. For example, an individual may pay a smuggler for his or her services to gain entry into a country. Once in the country, the smuggler may request additional money. When the smuggled client cannot pay, the smuggler becomes a trafficker if he coerces the client to do something, such as prostitution, to gain the additional money. In the same way, an employer may exploit an individual, such as by expecting him or her to work for less than the standard minimum wage, but it becomes trafficking when the employer houses the employee and will not let him or her leave.

Size, Scope, and Patterns

The size and scope of the human trafficking problem throughout the world is unknown. Similar to other types of abuse, human trafficking remains hidden, thus underreported, as a result of victims' fear and shame. Estimates of the number of victims have ranged from a few thousand to many millions, but none of the estimates are based on reliable data. For example, 14,500 to 17,500 trafficking victims per year entering the United States has been widely used in estimates for several years. However, only approximately 300 to 500 victims per year have been identified through many sources (e.g., newspapers, court cases).

The solution to these unreliable estimates has been to collect data on actual cases, thus undercounting the problem. Although collecting such data is in its relative infancy, there are several known databases. The International Organization for Migration held a meeting of researchers in 2004 that has resulted in development of the most complete global database, with approximately 7,000 victims of trafficking listed as of 2005.

It is accepted that every country is involved in human trafficking as a country of origin, transit, or destination. However, some countries are more likely to be a country of origin (e.g., extreme poverty, war torn), while others are likely to be a transit country due to geographic location (e.g., Mexico, which borders the United States) or a destination country as a result of its relative wealth (e.g., United States, Italy, United Kingdom). Trafficking patterns vary across time and reports are often based on a few known cases. However, generally, trafficking origins often are found in situations of dire poverty, frequently a result of war or economic devastation. For example, in the aftermath of the economic devastation and the fall of the Soviet Union, many of the Balkan states became countries of origin, supplying desirable women for sex trafficking throughout the Mediterranean and European regions.

Profiles of Traffickers and Victims

While the profile of traffickers includes a wide array of actors and organizational types, much of the literature reports small operations consisting of one or two traffickers, often a male and female team. On the other end of the continuum is organized crime, with its structures varying from loose networks to hierarchical organized crime families. Several typologies have been developed in the literature, but one incorporates both the organizational type and structure with the potential economic gains. This typology describes the continuum as moving from a sole proprietor (e.g., one man prostitutes one female, one household has one domestic servant in debt bondage) to a cottage industry (e.g., one native man sends his “girlfriend” back to her country to recruit one or two more friends or family to be prostituted), to a mall (e.g., several cottage industries in close proximity that often share their trafficked victims when the demand is high to

maximize profits), to the corporation (i.e., a highly structured organization with many victims). Women, as willing and/or unwilling partners, are often used in the recruitment phase, adding credibility to the deception involved in the process.

There is no universal profile of victims because of the wide variation in characteristics. For example, a child may be recruited by family members or community elders with the promise that the child will be given to a rich family and provided with an education and a skilled trade, but instead the child is sold into a life of pornography, sex tourism, or harsh labor. On the other hand, a woman may be recruited for prostitution or domestic service. Identification of victims is most effective using indicator characteristics. Indicators of trafficking include lack of freedom of movement, abuse, lack of personal documents, and an exaggerated fear response. For example, victims may be found living in rooms adjacent to massage parlors or under guard in an apartment or home. They are seldom seen in public and are frequently escorted when outside the work environment. In addition, many victims have untreated health needs.

Responses to Human Trafficking

The complexities involved in this covert crime necessitate that responses to human trafficking take a multidisciplinary approach to ensure their effectiveness. From a supply perspective, strategies that interrupt the “push” factors are likely to be effective. For example, extreme poverty without local employment opportunities and the perceived increase in the standard of living in foreign countries, combined with having children and no husband, have pushed young women to seek employment outside their home country. This desperation leaves the women vulnerable to those who come with promises of employment and a better life. Coupled with the fact that traffickers are often women from the home country, often from the same city, the promises are believable. Public awareness programs targeting these women are likely to assist them in making different choices.

From a demand perspective, strategies that interrupt the “pull” factors are likely to be effective. Demands often take the form of a general desire for cheap labor to decrease the prices and increase the profits on goods and services, as well as the desire

for sex. Public awareness and public shaming about forced labor (e.g., the Prohibition of Acquisition of Products Produced by Forced or Indentured Child Labor has resulted in a list of products produced using forced labor and the related country) are believed to be effective in reducing the use of this type of labor among major corporations. Other examples of demand reduction activities in the United States include prosecution of those who go abroad for sex tourism and “john” schools that educate males on the harm inflicted when they enlist the services of trafficked prostitutes.

Prevention efforts are focused on those who are most vulnerable (e.g., conflict zones) by increasing general awareness. Protection of the victims comes in many forms. Victims are often threatened by their traffickers, and their families are in danger. The Trafficking Victims Protection Act (TVPA) provides funds for victim assistance, including medical and mental health assistance, as well as T-visas that allow a trafficked victim and his or her family to live in the United States if he or she assists in the prosecution of the trafficker. Prosecution of traffickers has been plagued with problems, including insufficient evidence to prove the act of trafficking, difficulty in identifying the victims, and the general lack of awareness of human trafficking in law enforcement, the courts, and the jury pools.

The United States has responded to human trafficking with vigor since 2000. In October 2000, the TVPA became law, and in 2003 and 2005 its mandates were renewed. The 2000 legislation created the Office to Monitor and Combat Trafficking in Persons within the U.S. State Department. The 2003 legislation included a presidential initiative with \$50 million to support the development of multidisciplinary trafficking task forces, external research, and other activities. The 2005 legislation called for a biennial report on the state of human trafficking research.

In 2001, the U.S. State Department began producing the annual *Trafficking in Persons Report*, which ranks each country into three tiers according to compliance with the minimum standards for the elimination of trafficking. Self-assessment of the United States is not included in the *Trafficking in Persons Report*, due to the appearance of bias. Instead, the U.S. Department of Justice issues an annual report on the activities of the United States.

Other countries have responded to the call to action housed in the Protocol. For example, Lebanon

has completed its country assessment with the assistance of funding from the United Nations. The findings of the assessment indicate that the current penal code has all of the component laws necessary to prosecute traffickers, but lacks an overarching law labeling the aggregate behavior as human trafficking with the associated severity of penalties.

I

IDENTITY THEFT

Identity theft—the theft or unauthorized use of personal or credit information—is a relatively new form of crime that can result in its victims having to spend thousands of dollars and years of their lives restoring their good names. Little research has been conducted on this crime, so it is not well understood. This entry discusses the multiple definitions of identity theft, its prevalence and consequences, and legislative responses to it. It also presents findings from the first ongoing data collection of identity theft in the United States, the National Crime Victimization Survey (NCVS). Findings from 2005, the first full calendar year of data collection using the survey revealed that 5.5% of all U.S. households had experienced this crime.

Definitions

In 1998, Congress passed the Identity Theft and Assumption Deterrence Act (U.S. Public Law 105-318). Prior to this act, the victims of identity theft were seen as the businesses that suffered losses (such as bank and credit card companies) rather than the individuals whose identifying information had been used to commit the theft. Although this legislation aided prosecution of cases involving harm caused to individuals, the legislation is so broad that it did not serve to tighten the definition of identity theft for the research community.

There is no one universally accepted definition of *identity theft*, as the term describes a variety of

illegal acts involving theft or misuse of personal information. Under the Fair Credit Reporting Act, identity theft is defined as the use or attempted use of an account or identifying information without the owner's permission. Using this guiding legislation, the Bureau of Justice Statistics added identity theft to the household portion of the ongoing National Crime Victimization Survey that collects data from over 40,000 households twice a year. For the NCVS, identity theft was defined as including three behaviors: (1) unauthorized use or attempted use of existing credit cards, (2) unauthorized use or attempted use of other existing accounts such as checking accounts, and (3) misuse of personal information to obtain new accounts or loans.

Prevalence

In 2005, 6.4 million U.S. households discovered that at least one member of the household had been the victim of identity theft during the preceding 6 months. This figure represents 1 in 20 households in the United States. Victimization rates vary depending on the type of an identity theft. Thus almost half (46.2%) of victimized households experienced unauthorized use of an existing credit card, whereas a quarter (24.7%) experienced unauthorized use of other existing accounts. Misuse of personal information, or the form that some argue is “true” identity theft, was experienced by about 1.1 million households, representing one in six victimized households.

Not all households in the United States are equally likely to experience identity theft. The

households most likely to experience any form of identity theft are those headed by the youngest members (those 18–24 years old), in urban or suburban areas, in the West, of non-Hispanics, and with the highest incomes (\$75,000 or more). Households headed by persons age 65 or older and by those earning less than \$50,000 have victimization rates that are at least half those of younger or more affluent households.

Of great importance to the public is how identity theft is detected, as Americans' focus is on preventing such theft or mitigating the extent of damage. The most common way households became aware of the identity theft was by missing money or noticing unfamiliar charges on an account (30.8%). One fifth of victimized households discovered the identity theft when someone was contacted about a late or unpaid bill. For 1 in 20 households, the identity theft was detected by noticing an error in a credit report, noticing a missing credit card or checkbook, or having an account blocked by the issuer.

Consequences

Examples of problems that can arise as a result of identity theft include having banking problems, being contacted by a debt collector, or even paying higher interest rates. Overall, in 2005, one in five households experienced some type of problem as a result of the identity theft. Households with theft of existing credit card accounts were the least likely to experience problems associated with the identity theft (9%), while households that experienced misuse of personal information were more likely to experience problems than households with unauthorized use of other existing accounts (33.7% vs. 18.0%).

When examining time spent resolving all problems associated with the episode of identity theft, households report two extremes of time spent. More than a quarter (28.6%) of victimized households were able to resolve all problems within one day or less. Households that experienced unauthorized use of credit card accounts were more likely than households victimized by other types of identity theft to spend a day or less resolving problems (36.5%). At the other end of the spectrum, 17% of victimized households report having to spend one month or more resolving all problems.

More than two thirds of victimized households reported a financial loss of \$1 or more as a result of the identity theft. This figure is limited to only the most recent loss if a household reported discovering more than one episode during the preceding 6 months, and costs or losses to businesses may or may not be included. The remaining households reported not experiencing any loss (18.3%) or did not know the amount of the loss (12.9%). In 40% of the victimized households, the dollar loss was less than \$500. About 5% of the victimized households sustained a loss of \$5,000 or more.

Policy and Legislation

Identity theft has come to the attention of policy makers and the public over the last decade. In 2004, the Identity Theft Penalty Enhancement Act, which carries a mandatory 2-year prison term, was signed into law. In addition, President George W. Bush established the President's Task Force on Identity Theft on May 10, 2006. This interagency task force examined the problem of identity theft and the federal response to it, and released a list of recommendations. The work of the task force has been compiled in the report *Combating Identity Theft: A Strategic Plan*, released in 2007, which provides guidance for federal agencies involved in preventing, responding to, and investigating the problem of identity theft.

One of the recommendations in the strategic plan is for the Federal Trade Commission and the U.S. Department of Justice to work together to better understand the scope of the problem. With funding from both agencies, a supplement to the NCVS was administered for the first 6 months of 2008. The Identity Theft Supplement collected detailed information about the offender, interaction with credit reporting agencies and financial institutions, emotional response of the victim, financial loss, and risk avoidance. Findings from this supplement are expected to be released in 2010 and represent the culmination of coordinated efforts of several federal agencies to bridge knowledge gaps and better understand the problem of identity theft.

IMMIGRATION AND VICTIMIZATION

Understanding the victimization of immigrants was of great importance to pioneer victimologist Hans von Hentig, who listed "the immigrant" as one of thirteen categories in his 1948 typology of victims. As an immigrant himself, he knew how vulnerable immigrants can be. He described the experience as a temporary reduction to an extreme degree of helplessness in human relations. Despite von Hentig's interest, victimologists did not pursue the topic until recently. The new interest in immigrant victimization is usually billed under more politically compelling rubrics like trafficking of human beings, hate crime, or domestic abuse, or it is recast in terms of studies of race, ethnicity, nationality, or religion. These labels are expedient for research purposes, but they do not address the fact that being a foreigner and a minority member makes an individual a more vulnerable target for victimization than does just being a minority member.

Patterns of Victimization

There is considerable evidence that immigrants suffer higher rates of victimization than autochthons for both violent and certain property crime. They also suffer other types of victimization, including theft of wages, fraud, labor and housing violations, economic exploitation, trafficking in humans, and hate crime. In terms of common crimes of violence and property crimes, immigrants are more likely to be victimized by their own people than by autochthons.

This varies, however, depending on the type of crime and the gender of the victim. The patterns of victimization fit well with opportunity and conflict theories. Immigrants are suitable targets who are accessible and often have no guardians—unless they are living in enclaves. The vulnerability of immigrants who are illegal is even greater. The fact that a person is a foreigner and/or has ethnic characteristics that make him or her seem "foreign" incites some people to hate crime. Immigrants living in close proximity to high-crime-risk areas are more likely to be victimized. In general, the same sociodemographic characteristics associated with being a criminal are associated with being a victim of crime.

Immigrants have been found to be at higher risks than autochthons of being the victims of homicide in Australia and in the United States. Australian homicide victimization rates for various immigrant groups, calculated as age–sex standardized mortality ratios (SMRs) using the Australian-born rate as the standard, show that male SMRs ranged from 0.13 for immigrants from Africa and the Americas to 5.83 for Koreans.

California death certificates show that among residents who died of homicide in the 1990s, foreign-born persons were overrepresented. Risk rates varied by ethnicity and across time. Foreign-born Whites, Hispanics, and Asians were at significantly higher risk, while foreign-born Blacks were at a statistically similar risk of homicide compared with their U.S.-born counterparts.

Using 1999 Italian data, Marzio Barbagli distinguished between immigrants from developed and those from developing countries, and he calculated the risk of victimization for these two groupings compared to the risk for Italians (Italian = 1). Immigrants from developing countries had risks that were higher than both Italians and immigrants from rich countries for six crimes (burglary, purse snatching, robbery, aggravated assault, sexual assault, and homicide). They had lower risk than both immigrants from developed countries and Italians for auto theft and shoplifting. They were more than five times more likely than Italians to be pickpocketed, but half as likely to be pickpocketed as were immigrants from wealthy countries. With regard to homicide, they were 3.32 times as likely as Italians and 10.3 times as likely as immigrants from rich countries to be victims.

Victim surveys for 1990 and 1992 in Sweden found that immigrants had higher rates of victimization than native Swedes for three forms of violent

crime (violence causing death, serious violence, and threats of violence), but not for theft and property damage. Certain factors increased victimization rates among both immigrant and indigenous groups—specifically, being young, being single, living in public housing, and living in an urban environment.

Dutch studies from the 1990s showed that ethnic minorities (i.e., immigrants) were twice as likely as the entire city populations to be the victims of threats of violence and one-and-a-half times more likely to be victims of property crimes. Comparing the responses of Turks and Moroccans with those of a “matched” Dutch group who lived in the same neighborhoods, however, the immigrants appeared to be less often the victims of violent and property crime. Another study found no significant differences in general victimization rates of immigrants and natives living in the same neighborhoods.

Many studies have shown that immigrants are more likely to be victimized by their own kind than by autochthons. A simulation estimated that if foreigners were only 3% of those charged with homicide in Italy, the rate of victimization of immigrants would be reduced by 50.8%, while that of Italians would be reduced by only 2.3%. Of immigrant victims of homicide in Australia, 51.3% were killed by their compatriots. This varied from zero for New Zealanders to 100% for immigrants from the Middle East.

The terrorist attacks in the United States and the United Kingdom spawned a surge of retaliatory hate crimes against foreigners. Hate crime against immigrants, however, was commonplace before terrorism. Mary Beth Sheriden has reported that immigrants are regularly cheated by employers and defrauded by labor recruiters.

In major countries of destination, women immigrants from around the world share common characteristics of vulnerability and disproportionately high rates of abuse. Numerous studies document this vulnerability for women in situations involving domestic abuse, “mail order brides,” and human trafficking. In Sweden, for example, women with foreign backgrounds were found to have an 80% greater likelihood of being “victims of violence indoors” (an indirect measure of domestic violence) than are native Swedish females. Ironically, immigration policies often make immigrant women suffer their domestic abuse without protest by giving their spouses the power to have them deported.

The trafficking of human beings for sexual or labor exploitation reappeared on the agenda of the international community in the 1990s. Although the official estimates of the number of cases of trafficking appear to be seriously inflated, there is no doubt that the practice is a large and vicious one. Domestic abuse among mail order brides in the world is believed to be increasing. Filipina “mail order brides” in Australia have been found to be at extraordinarily high risk for violence and murder—almost six times more likely than other women to be victims of homicide.

The victimization of many immigrants begins even before they set forth on their journey. Predators of all kinds lie in wait. Labor recruiters lie to them. Bandits, police, immigration officials, shopkeepers, bus drivers, smugglers, and traffickers extort bribes, inflate prices, beat them, leave them to be cooked to death in locked vehicles abandoned in the desert, and exploit them in numerous ways.

IN-CAMERA PROCEEDINGS

A significant characteristic of the criminal justice system in the United States is its openness. There are no “star chambers” that operate out of the public view and behind closed doors. The televised trial of O. J. Simpson for the murders of Nicole Brown Simpson and Ron Goldman is an example of the public nature of such proceedings. Not only were the proceedings reported each day in the press, but the trial was carried live on television. There are also numerous books that have been written as a result of the trial. The private lives of Simpson, Brown Simpson, and Goldman were displayed before the world. However, the question remains as to whether every portion of every trial should be played before the public and/or a jury. In-camera proceedings—where a matter (usually a question of law or discretion) is heard in private, in the judge’s chambers—are an alternative approach.

The victims of crimes come to court having already been harmed. The legal system is designed to provide a remedy, not only for the victim, but for the good of society and, it is hoped, the system will not exacerbate an injury or cause another. The remedies available to society are to punish the person who commits the crime, prevent similar crimes from occurring, and attempt to make the victim whole again. Despite these objectives, many victims and their families will forever bear the scars of the crimes that are committed against them.

The issues addressed in in-camera proceedings may be preserved on the record (i.e., recorded as a part of the trial transcript outside of the jury) or off the record, where only the outcome becomes part of the court record. It is important to note that the proceeding is not *ex parte* (i.e., one in which only one side is present), thus counsel for both parties to the dispute are usually present. Matters that are likely to be addressed may involve testimony of a rape victim or child, past sexual activity of the victim, the propriety of crime scene or autopsy photographs, expert testimony, medical information, informant testimony, informant identification, admissibility of evidence, national security information, review of an attorney’s work product, motions to sever the trials of defendants, grand jury minutes, and other similar topics. While this may sound like the star-chamber proceedings that operated behind closed doors of 16th-century English courts, it bears little resemblance to those proceedings.

There have been several recent cases in the news involving in-camera proceedings. The first one involves the use in court of testimony of an alleged rape victim’s past sexual history and the other involves the use of intelligence (national security and/or source) information in a public trial. The first case involved basketball star Kobe Bryant.

Bryant was accused of the sexual assault and rape of a 19-year-old woman who was an employee of the facility where he was recuperating from knee surgery. There were numerous pretrial hearings that the court held in chambers regarding sensitive private information. Among the matters discussed in-camera were evidence concerning a waiver of the victim’s medical and/or mental health privileges and the admissibility of evidence contrary to a Colorado rape shield statute. These hearings were held to determine if otherwise private information regarding the accuser would be released to the defendant and, later, be admissible in court during the trial. The concern here is whether a victim of an alleged sexual assault and rape must suffer additional harm by being opened up to public scrutiny of personal and/or private matters regarding sexual activity and medical treatment. Should the nature of a rape charge automatically result in the waiver of any physician–patient privilege? And how much of the victim’s private life should be open for scrutiny as a result of coming forward to the police about the assault?

However, it should be noted that the concern for the privacy of the accuser needs to be balanced with the Sixth Amendment guarantees to an accused of impartiality and due process. In particular, the concern for a crime victim's privacy must be balanced with the defendant's right "to be confronted with the witnesses against him," as set forth in the Confrontation Clause of the U.S. Constitution.

There were similar issues presented in the case involving three Duke lacrosse players and an exotic dancer who was hired to entertain at a party they attended. In order to provide a full defense, there were motions by the defendants to disclose her past sexual activity and medical information, particularly on the night of the alleged crime. As in most cases involving such sensitive information, courts are inclined to examine facts and rule on such evidence in chambers and outside of public view. In chambers, only the judge makes the initial review of the material that the defense requests.

In some matters concerning national security, the court has also seen it appropriate to examine material in-camera. Litigation in cases involving national security information may be the result of criminal charges regarding terrorism or espionage, or simply a government agency's response to a Freedom of Information Act request. The burden of denying the existence of information based on national security is on the agency. In such a case, the agency will ask the court to review in-camera, in private, a "classified" document or an affidavit as the basis for withholding documents pursuant to the request. In the case of *Vaughn v. Rosen*, 157 U.S. App. D.C. 340, 346, 484 F.2d 820 (1973), the court determined that a public record of the justification for withholding the information "would compromise the secret nature of the information." *Hayden v. National Security Agency* (197 U.S. App. D.C. 224, 608 F.2d 1381 [1979]) noted that the submission of in-camera affidavits and a discussion regarding the request are most likely to occur in matters involving national security.

The court system functions to preserve rights and remedy wrongs, and the techniques it uses prioritize pursuit of this goal. The courts effectively use in-camera proceedings to ensure that liberty and justice are maintained and that the rights of the people under the U.S. Constitution have been preserved.

INCEST

In the 1940s psychoanalysts began looking at cases of incest, especially those of father-daughter incest. However, the first in-depth examination of incest did not occur until 1955, when sociologist Kirson S. Weinburg completed his research on the topic. Even after Weinburg's study, however, cases of incest were believed to be uncommon—until a shift from this belief occurred in the 1970s. Currently incest is viewed as more common than reports show and as a prevalent sexual crime against adolescents and young children.

Definitions

The definitions of incest vary. However, incest is often classified as any sexual contact (e.g., touching, fondling, oral sex, verbal seduction or abuse, and/or intercourse) between closely related persons (often within the immediate family) in which an adult coerces a child or adolescent or an older child coerces a younger child. Under this definition, incest includes father-daughter, stepfather-daughter, mother-son, stepmother-son, sibling-sibling, and extended family-child incest. The majority of reported incidents of incest occur between fathers and daughters and stepfathers and daughters (however, it is believed the true rate of sibling incest is underreported). Based on the majority of the information currently available, the most often discussed incidents of incest are those between a paternal figure (e.g., father or stepfather) and a child, thus this entry sometimes refers to the perpetrator of incest as male.

Prevalence

Determining the number of incidents of incest within the United States is a difficult task. This void in information can be attributed to a number of different factors, the most significant of which is that incest remains highly underreported. Victims of incest are extremely reluctant to reveal the abuse occurring against them because of fear, shame, and blame. Nevertheless, incest has still been cited as the most common form of child abuse. In addition to being severely underreported, accurate rates of incest are also difficult to ascertain due to differences in definitions and methods of data collection and sampling. To the detriment of investigations of the prevalence of incest, research often fails to distinguish between familial child abuse and nonfamilial child abuse. Thus, though there is not an accurate prevalence rate for incidents of child incest, it is recognized that this is a significant crime that needs significant attention.

Occurrence of Incest

Incidents of incest occur when someone uses a position of power, emotional manipulation, and threats to achieve the goal of sexual satisfaction. Incidents of incest often do not include physical force or coercion; however, the perpetrator's use of verbal threats is a common strategy used to coerce the child into committing the desired behaviors. Using verbal threats allows the perpetrator to guarantee the silence and compliance of the child victim. This manipulation may include threats of family division or dissolution and/or termination of the relationship between the child and perpetrator, and it often evokes personal shame or blame in the child. In addition, the perpetrator may threaten to harm himself, the child, or other family members if the acts of incest are revealed or discontinued.

There is no particular length of time that incest lasts. The occurrence of incest may be a single act, or it can span decades. Incidents may be occasional, or may be compulsive in nature and occur numerous times a day. While incest is believed to occur more often in families of lower socioeconomic class, in ethnic minorities, and in rural families, those beliefs have not been adequately supported by research. Rather, a more likely premise is that incest occurs in all types of families regardless of

sociodemographic factors (e.g., socioeconomic status, ethnic origin, or geographic location).

Incest remains one of the most underreported and least discussed crimes in the United States. Victims of incest employ a number of coping mechanisms to manage the emotional and psychological consequences of incest (e.g., guilt, shame, and fear). In addition, victims often deny the incidents or dissociate from the incidents in order to minimize or normalize the acts perpetrated against them. These strategies often prevent them from coming forward or reporting the crimes. Finally, victims are often too frightened to report incest. Because the perpetrator is often a person in a position of power over the victim, the coercion and fear tactics used against the victim are often successful (i.e., the victim declines to report the incest, and thus the perpetrator is free to continue his crime).

Effects of Incest

The act of incest leads to a number of short-term and long-term individual and social consequences. For example, girls who experience incest have higher rates of risky behaviors (e.g., running away, suicide attempts, and pregnancy). In addition, anxiety, panic, major depression, and alcohol abuse and dependence are significantly higher in victims of incest than in others. Moreover, posttraumatic stress disorder (PTSD) is common in incest victims. Finally, incest also has severe social consequences because it is considered socially taboo. Fearing the social reprisals enforced by society (e.g., social isolation and name-calling), incest victims often suppress and internalize the anger and shame they feel. This often leads to significant personal turmoil; thus, the need for intervention in the lives of victims of incest is often necessary and prevalent.

Response to Incest

Though incest is illegal in most jurisdictions, the definition and legal consequences of committing incest vary by country and, at times, between different states. In the United States, the states and the District of Columbia have individual specifications and statutes, but they all have some form of incest prohibition.

Currently there are few formal services available to victims of incest or their families. Resources for incest victims include books, self-help groups,

therapy programs, and limited legal responses. When cases of incest are reported, treatment often includes individual, family, couple, or group therapy for the offender, the victim, and other family members. All parties also are evaluated for preexisting and coexisting problems such as substance abuse, domestic violence, and psychiatric disorders. This type of intervention is critical because many men who sexually abuse their children often participate in other forms of sexual deviance.

Victims of incest face a long road toward recovery. Regardless of the factors surrounding a case of incest (e.g., the length of time, number of times, relationship between parties involved), the recovery process for the victim is extensive. It is evident that a greater number of services are needed for victims and their families. With increasing awareness of the issues of incest, including the related emotional, psychological, and physical consequences, it is imperative that greater resources be allocated for victims of incest.

INCIVILITIES/SOCIAL DISORDER

In the late 1970s, many researchers and policy makers interested in community crime prevention held out high hopes for crime prevention through environmental design (CPTED). Popularized by architect Oscar Newman, who borrowed the core of many of his ideas from urban writer and activist Jane Jacobs, the idea was that certain site-level

design features would facilitate specific behaviors of residents. These design features would result in the regulars or residents of the setting exercising both enhanced surveillance that would prevent crime and greater willingness to intervene in the event a crime occurred. The designs also would alter the perceptions of potential offenders about how good these locations were for criminal activity. The residents' or users' behavior and attitudes were subsumed under theoretical ideas like territorial functioning and informal social control. When delinquency was discussed, the process referenced was social disorganization. Research did show some of the expected connections between design and behavior in urban residential and public housing contexts, but the connections were not as strong or consistent across settings as had been previously promised.

Attention switched to a different aspect of the physical environment in the early 1980s—a broken window left unfixed. At a time when urban police departments were casting about for proactive roles, James Wilson and George Kelling suggested that unfixed physical deterioration in a neighborhood setting could undercut residents' willingness to intervene in situations and embolden potential offenders. They had police officers on foot, working collaboratively with resident and business constituencies, work to alleviate physical incivilities: graffiti, abandoned cars, litter, and the like. Social incivilities also were viewed as relevant and needing to be ousted; these included drunks, panhandlers, squeegee kids, and homeless people.

At about this same time several researchers were finding strong connections between residents' reports of physical incivilities, disorderly behavior by groups such as unsupervised teens, and reactions to crime like fear or avoidance.

Police and crime prevention specialists and resident improvement groups had a new target: disorderly neighborhood conditions, both social and physical. Their belief was that if they could just clean the place up, scrub out the gang tags, and get the drunks and dealers to hang out somewhere else, things would be fine. The balance of this entry looks at the efficacy of this approach to incivilities and social disorder.

Prospect of a Long-Term Solution

In the late 1980s, Wes Skogan expanded this core idea by suggesting that controlling incivilities

would be the key not only to making residents feel safer, but also to driving down neighborhood crime rates and preventing neighborhood decline. Entire areas of cities might be saved from decline and made safe through clean-up campaigns. Big city mayors signed on, including, among others, David Dinkins (New York City), Rudolph Giuliani (New York City), Kurt Schmoke (Baltimore), and Martin O'Malley (Baltimore).

At the time, zero-tolerance policies were considered the means of solving the problem of incivilities. The first zero-tolerance policies emerged from corporate work requirements. Organizations would have a zero-tolerance policy on drug use, for example. Implementing such a policy was relatively straightforward: The organizations would simply employ random drug testing.

However, implementing zero-tolerance *policing* strategies proved far more complicated for many reasons. Police cannot afford to cite or arrest every citizen for every violation or crime committed. They simply do not have the time or the proclivity for the paperwork. For many in the police, it is not their idea of "real" policing. In addition, most communities do not really want zero-tolerance policing. Historical research on what happened in some cities during Prohibition-era crackdowns on alcohol violations amply demonstrated that very few communities really wanted equal justice for all. This is probably still true. Therefore, inevitably, zero-tolerance policing amounts to geographically varying enforcement of different intensities around different neighborhood problems. Zero-tolerance policies, Australian researchers have suggested, when applied to open-air drug markets, can actually significantly elevate public health problems. These policies cause the markets to disperse, making it more difficult for public health workers to contact the addict population and carry out needle exchange programs, and increasing the chances that drug users will be "shooting up" in ways or under conditions that are riskier.

Empirical Work

The most recent solid empirical work has found only extremely modest beneficial impacts of zero-tolerance policing on later crime shifts. The studies have suggested that enormous police effort was required, either through citations or misdemeanor

arrests, to generate less than overwhelming crime prevention benefits.

In the mid-1990s, some work began on gauging the longitudinal effects of incivilities at both the street block and neighborhood levels in Baltimore, Maryland, and Salt Lake City, Utah. The analysis of street blocks suggested later changes in reactions to crime and local commitment sometimes were not shaped by earlier perceived incivilities but were contingent on other local features. The analysis of neighborhoods suggested modest and sometimes contingent effects of incivilities. The effects were contingent in that they depended both on the specific outcome and on the specific type of incivility indicator used.

Questions have also been raised about what assessed or perceived incivilities represent. Earlier research suggested they reflected underlying disorder in the residential setting. More recent work, however, has failed to find confirming patterns of convergent validity when multiple incivility indicators were used. A survey-based approach might ask residents to rate the intensity of local physical incivilities, like graffiti, vacant houses, litter, poorly maintained houses, and the like, as well as social incivilities, like unsupervised or rowdy teen groups, neighbors fighting, or public drunkenness or drug sales. Alternatively, trained raters can walk street blocks and count incivilities. They can do so reliably. From a construct validity perspective, the indicators of incivilities from different data sources should converge. However, sometimes they do not converge, especially when changes over time are examined. It is not clear what single or multiple underlying concepts these indicators are capturing, net of underlying socioeconomic and racial variations across contexts.

By the late 1990s, counterreactions to the sociopolitics of incivilities and zero-tolerance emerged. Bernard Harcourt suggested these zero-tolerance policies reflected a collapse of the harm principle, being disproportional responses to the harm occurring. Handing out stiff fines or even jail time to litterers and those urinating in public harkened back disturbingly to an era in the middle of the preceding century when vagrancy laws were widely used by police to remove "undesirable elements" from their locale. Harcourt also suggested these policies widened social divisions. Ralph Taylor has argued that zero-tolerance policing policies represent a return

to the harsh policing practices seen in large cities in the early 1960s and are based on fundamentally flawed or at least unsubstantiated program logic models. Martin Innes, returning to a symbolic interactionist argument made 30 years ago by Albert Hunter, has argued that the same incivility can have markedly different meanings for and effects on different groups of people or even different individuals, suggesting it will be difficult figuring out which incivilities to target.

Current Status and Future Outlook

Where does this leave us in solving the issue of incivilities and social disorder? The situation can be examined from the policy side, the prevention side, and the theory side.

In terms of policy, draconian enforcement of laws or regulations targeting disorderly behavior or deteriorating physical conditions will probably continue to be popular, in large part due to the politically asymmetrical consequences surrounding this debate in an era of late modernity, as described by David Garland. To favor less enforcement is to appear soft on crime. Appearing soft on crime can lose elections.

The popularity of these policies will continue despite weak empirical support suggesting that these policies, *in the long term*, are unlikely *on their own* to result in significant crime or victimization prevention. Targeted enforcement, third-party policing, or saturation of places with police can have a dramatic impact for a short period, but it is not feasible to keep up such a dramatic response over time. Most of the work on crackdowns shows short, temporally limited effects. The effects of enforcement against incivilities are probably the same.

Prevention and reduction of incivilities cannot work in the long term for several reasons. First, as intimated above, the agency resources are not there. Police cannot make and keep this a high priority over an extended area for an extended time. Second, if these problems crop up in a location, the occurrence is probably overdetermined. Crime pattern theory, and environmental criminology more generally, have demonstrated over the last three decades that local social, economic, household, land use, site, land, and traffic arrangements strongly shape what crime problems will crop up where. Barring wholesale forced out-migration of

residents, wholesale reconstruction of segments of neighborhoods, or changing large numbers of non-residential land uses and rerouting traffic, the long-term differentials in crime across areas of a city or of a neighborhood will remain.

In terms of theory, three broad issues remain unresolved. First is the construct validity question around incivilities. Do they reflect underlying disorder? With ecological units of analysis, incivility indicators do not converge as expected across method types. Are perceived incivilities or assessed incivilities separable from low-level misdemeanor rates of a locale? At the individual level, no one has yet demonstrated discriminant validity of perceived incivilities from mental health indicators like anxiety and depression, or from reaction to crime and local attachment to place indicators. Thus, at the psychological, small group (street block), and ecological levels, a successful case has not yet been made that variations in incivilities *primarily* reflect variations in an underlying unitary construct called disorder. Second, continuing confusion surrounds the relevant psychological and behavioral processes that lead incivilities to have the impacts they do. Different labels have been applied to the relevant processes—informal social control, willingness to intervene, collective efficacy, human territorial functioning—but clear longitudinal demonstrations at different levels that these processes are affected by incivilities, *net* of other fundamental sociodemographic and physical site features, are lacking. This is parallel in some ways to the early arguments about defensible space and territorial functioning. Defensible space was theorized to dis-inhibit residents' territorial cognitions and behaviors. In an opposite way, incivilities are theorized to inhibit some of those same cognitions and behaviors. But data linking these two—changing incivilities and changing territorial indicators or social control indicators—are lacking.

INFANTICIDE

Infanticide is a serious problem, both in the United States and throughout the world. It is a serious crime that affects not only the victim and offender but society as a whole. This entry explores the definition of infanticide, possible explanations, prevalence and reporting issues, and the unique characteristics of the victims and offenders. It then discusses risk factors, prevention measures, and the particular punishments associated with this crime.

Definition

Infanticide is generally defined as the intentional killing of an infant. Although the precise age of the victim that is required to qualify a murder as infanticide

varies, in the United States it is generally accepted that children under the age of 1 who are murdered are classified as infanticide victims. Other definitions may include murder of a child under the age of 5. Neonaticide, or the killing of a newborn within 24 hours of birth, is a specific type of infanticide. The most common perpetrators of infanticide are the infant's parents, which also classifies the homicide as filicide.

Explanations

Infanticide has been a somewhat common practice throughout history. In ancient times, it often took the form of child sacrifice for religious or supernatural purposes. Infants who were unwanted by their parents were often subjected to abandonment and subsequent death by exposure to the elements. Early cases of infanticide were partially legitimized by the existing societies because of the belief that newborns were not considered human.

Although many documented cases of infanticide are tied to psychological, sociological, or criminological explanations, other explanations are relevant. Residents of some countries may practice infanticide as a means of population control, especially against female infants. In countries where a limitation is placed on the number of children that a family may have, parents, immediate and extended family, and community members often prefer the production of male children, and decide to destroy the female children upon or shortly after birth. The level of social acceptance of this practice varies by country. Feminist scholars have suggested that the regulation of gender demographics through the controlling of births through "reproductive work" plays a pivotal role in shaping women's societal roles. In some countries, the exploitation of women through reproductive work may be used as a sociopolitical means to control the gender demographics, thereby maintaining the male-dominated power structures. The control exerted through formally and informally enforced gender preferences may be connected with rates of infanticide as well.

Prevalence

The rate of homicide of children under the age of 4 in the United States ranks among the highest

rates of child homicide in the world. In the United States, between 600 and 700 children under the age of 5 are killed annually, and about 45% of all child murders are classified as neonaticide cases. However, the actual prevalence of infanticide is difficult to determine, as it often resembles other forms of death among infants. For example, sudden infant death syndrome cases include children who stop breathing in their sleep, whereas shaken baby syndrome includes cases in which a child is shaken and suffers internal bleeding or swelling. Because it is difficult for policing agencies to make these determinations, incidents that may be infanticide cases may be officially classified as either accidents or deaths from natural causes. Furthermore, the reliability of system-detected infanticide cases hinges on official government recognition of a child's birth. In countries or specific regions within countries where record keeping is lacking, or childbirth frequently occurs outside of medical facilities, there may be no way of detecting cases of infanticide short of parents' self-reports.

The only major reporting tools that currently exist in the United States to measure infanticide are those of the Uniform Crime Reporting Program and the National Incident Based Reporting System, both of which rely on official reports of infanticide as documented by law enforcement agencies. For the reasons stated above, these numbers are not necessarily reliable. The National Crime Victimization Survey cannot be used to capture unreported infanticide, as the victims cannot be surveyed.

Victims and Offenders

When dealing with any type of family violence, it has been noted that there is a positive correlation between the age of the victim and the social distance between the victim and the offender. For child homicide cases, this means that the youngest victims are likely to be killed by parents, babysitters, or other caregivers. Of all the age groups, children under the age of 5 are the most likely to be killed by a parent or guardian, in part because these young children spend most of their time with their parents and guardians. Once children reach age 5, they spend more time with people outside the family, which means that other individuals, such as teachers and friends, may be inclined to

notice warning signs of abuse that might lead to murder. The second largest group responsible for infanticide are those persons classified as friends or acquaintances; a group largely comprised of boy-friends of the victims' mothers. Similar to many types of violent crime, a very small percentage of infanticides are committed by strangers.

However, infanticide has some unique characteristics not shared by other types of violent crime. Unlike many other forms of murder, females make up a significant portion of the perpetrators, with many acts being committed by the mother of the victim. Also, nearly all cases result from the child being beaten, strangled, shaken, drowned, or suffocated, which is in sharp contrast to other forms of murder, in which firearms and knives are the most prominent weapons. This is in part due to the vulnerability and relative small physical stature of the victim, who is rendered defenseless against the perpetrator.

Risk Factors

One risk factor associated with infanticide is the age of the parent, and more specifically, the age of the mother. Very young mothers may be experiencing denial, or find themselves overwhelmed or unprepared for their new motherhood role, thus cases of neonaticide are often linked to the young age of the mother. In particular, severe cases of postpartum depression may lead a mother to feel unable to care for her child. Several high-profile cases of murder committed at the hands of the child's mother have brought increased attention to this facet of infanticide.

Other factors, such as poverty, unemployment, and divorce may be indirectly linked to infanticide. These issues often create an increased strain in the household, leading to stress among parents. Parents experiencing higher levels of stress as a result of challenging situations may be violent with their young children and even homicidal. This is not to suggest that "broken" families or those living in poverty are more likely to commit infanticide, however, as other stresses may equally cause other types of families to exhibit risk factors.

One commonality often observed among victims is a history of being abused. Many cases are the result of a pattern of abuse in which the parent or other caregiver was reacting violently to a newborn or child. Among children who are abused, the

most frequent cause of death is a physical injury to the head.

There may also be a link between the race of the child and the likelihood of being a victim of infanticide. Black children are disproportionately represented and make up a majority of infanticide victims. In contrast, children who are either White or classified as “other” races make up the minority of reported cases. This may be the result of the issues discussed above, however, such as poverty, unemployment rates, and young parents. These statistics also should be considered with caution because the numbers are based on official police reports and subject to reporting errors.

All of these risk factors contribute to the consideration of infanticide as a social issue. More importantly, it should be understood that the media may play a role in conveying information to the public on these risk factors. As with all violent crime, the news media may disproportionately cover particular stories, especially those that are not the typical case. As such, it may be that stories in which the victims and offenders do not fit the profile of the standard infanticide case are actually more likely to receive widespread media coverage, thereby creating a skewed view of the issue.

Prevention

Because a great number of infanticide cases result from physical injuries inflicted on children by parents or caregivers, preventive measures should focus on these individuals as potential offenders. Possible measures include parenting classes (both before and after the birth of a child) and increased involvement of child protective agencies for cases deemed “at risk.” However, like all forms of homicide, infanticide is often situational rather than premeditated. Furthermore, the risk factors associated with infanticide are highly complex, making it difficult to adequately predict potential offenders and victims. Risk factors may be multidimensional, meaning that it may not be psychological or sociological factors alone but combinations of these factors that lead to the crime.

A common response to the issue is child death review teams, which are multidisciplinary investigation teams. These teams are becoming more prevalent, especially in the United States and Canada, and fulfill various duties. Their primary

function is often to examine death cases, seeking common patterns. They also often serve as a policy analysis and review board, examining the potential role of Child Protective Services in preventing deaths among children, as well as furthering the understanding of risk factors associated with child homicides and deaths.

In an effort to decrease homicides of infants, many states have passed legislation to allow parents to leave unwanted babies in designated safe locations, such as hospitals or fire stations, without a fear of legal action. These measures may help some of the individuals who are at a high risk of committing infanticide, such as those who do not feel they are economically or psychologically prepared to care for their children. Generally, states allow a grace period for either parent to claim the child before parental rights are terminated.

Punishment

Infanticide is a type of homicide, and is therefore subject to an individual state’s or jurisdiction’s homicide sanctions. These punishments range in severity, but can include the most severe punishments, such as lifelong prison sentences and capital punishment. Capital punishment statutes may be particularly relevant for infanticide cases, as many states that use the death penalty have specific provisions for those who murder very young victims. Trends in punishment indicate greater leniency for maternal offenders, who often are sentenced to probation or receive suspended sentences, while paternal offenders often receive more harsh punishments.

“Failure to protect” laws may also be used against parents as a means of offering protection to the abused child. Parents who did not murder their child, but who also did not prevent abuse by the offender, can be charged under these laws. These laws are viewed as punishing those who did not murder or abuse the victim, including those suffering from battered woman’s syndrome who felt unable to prevent or report the abuse of their children. As such, these laws are controversial and receive mixed levels of support.

INNOCENCE PROJECTS

A network of innocence projects has emerged in the United States, Canada, Australia, and the United Kingdom to address the problem of wrongful and unlawful conviction. Driven by the belief that *if the wrong person is put in prison, the actual perpetrator of harm is free to commit more violent crimes*, innocence projects exist to correct miscarriages of justice leading to wrongful and unlawful convictions.

When the wrong person is put in prison, we systemically generate two victims—the actual victim of the original crime and the victim of a conviction for a crime he or she did not commit. This entry explores the role of innocence projects as a vehicle for righting the injustice of wrongful and unlawful conviction.

Definitions

Wrongful and Unlawful Conviction

In the United States, when scholars speak of wrongful and unlawful conviction, they are referring to the conviction of a person who is actually innocent of the crime for which he or she has been charged. Simply put, the person didn't do it; someone else did. Asserting that a *wrongful conviction* has occurred impugns no one. It says nothing

about the motivations of law enforcement, prosecutors, defense attorneys, or forensic analysts. By way of contrast, to allege that a suspect has been the victim of an *unlawful conviction* is to identify a case where police officers, prosecutors, and forensic analysts knowingly engaged in illicit behavior. At issue is the question of intention. As human beings, despite our best efforts to the contrary we will make mistakes. In those cases where a criminal justice practitioner professionally, but erroneously, proceeds to convict an actually innocent person, it is referred to as a *wrongful conviction*. Errors of judgment or omission can plague the best investigators, prosecutors, defense attorneys, and analysts. Conversely, to knowingly and willfully participate in the *unlawful* conviction of an innocent man or woman is a pernicious abuse of power, a threat to jurisprudential legitimacy, and a violation of human rights. Innocence projects work to correct both wrongful and unlawful convictions, and try to determine the causes of each.

Legal and Actual Innocence

It is important to distinguish between two common legal references to the notion of “innocence.” Attorneys and judges may refer to a defendant as either *legally* innocent or *actually* innocent. The accused in a criminal case can be considered *legally* innocent if he or she has been found “not guilty” by a judge or jury. That is, a jury could not determine beyond a reasonable doubt that the defendant was responsible for committing the crime of which he or she was accused. By way of contrast, actual innocence is the absence of guilt; it is the absence of facts that in any way implicates a suspect with having involvement in a criminal event. Plainly speaking, the accused person who is *actually* innocent was not involved in any way with the planning and carrying out of the crime.

What Is an Innocence Project?

Innocence projects are organizations created for the purpose of investigating cases on post-conviction review (PCR) where actual innocence is being alleged. Post-conviction review is provided for under Rule 32 of the *Federal Criminal Code and Rules*, which provides for judicial

consideration of constitutional errors that occurred at trial as well as newly discovered evidence. Innocence projects typically do not get involved in cases prior to the exhaustion of state appeals, so in that way they are seen as the last resort for petitioners who believe they have been wrongfully and unlawfully convicted. Thus far, four innocence project models have emerged in the United States: (1) university based and operating within a law school; (2) university based, combined social science and/or humanities department and law school students and faculty; (3) university based but with no law school affiliation; and (4) community based.

With the exception of the fourth model—the community-based innocence project—the majority of innocence projects operate out of higher educational settings, including both undergraduate and graduate programs. The greatest proportion of innocence projects operate as part of law school clinics. One of the oldest and most successful models combines journalism and law school students at Northwestern University to divide the labor. Undergraduate journalism students investigate cases and turn the case material over to the law school to write PCR briefs. For universities with no law school, but where the faculty expertise exists to operate an innocence project, the third model has proven to be a viable option. At Northern Arizona University in Flagstaff, Arizona, the Northern Arizona Justice Project (NAJP) operates out of the Department of Criminology and Criminal Justice. Both undergraduate and graduate students, primarily in criminology and criminal justice, serve as student investigators. The NAJP receives legal advice and representation from volunteer attorneys living in Northern Arizona. Finally, highly successful innocence projects have operated entirely without university affiliations. Centurion Ministries was established in 1983 and is the longest operating and most successful project in the United States. In addition, the Innocence Project New Orleans is a very successful project that operates by combining the resources of a few paid staff and many volunteer investigators and attorneys.

Presently, there are 60 innocence projects located in 43 U.S. states. In addition, there are innocence projects in Australia, Canada, the United Kingdom, New Zealand, and Germany.

How Do Innocence Projects Work?

Innocence projects have adopted different criteria for the kind of cases they will agree to investigate. Some only investigate cases where DNA is available for testing. These are arguably the “easier” cases to work on, because DNA will determine with some certainty whether or not the petitioner was or was not a participant in the crime for which he or she was accused. However, DNA evidence only exists in about 10% of cases nationally. By far most criminal convictions are obtained without the use of physical evidence. To procure a conviction in these cases, prosecutors rely on some combination of eyewitness testimony, suspect confessions, the testimony of a jailhouse informant (snitch), and ineffective indigent representation. For a host of reasons, these cases are terribly difficult to investigate on post-conviction review. Innocence projects choose what kind of cases they will work on, but most will take both DNA and non-DNA cases.

Innocence projects receive hundreds, and sometimes thousands, of requests for assistance each year. To manage the influx of requests for assistance the projects have extensive screening processes that are used to identify cases where a viable claim of actual innocence exists. While there is local variation, most projects follow the process described below.

Inmate referrals usually appear in the form of a letter from another innocence project, a private attorney, or a family member or friend. If the referral comes from an innocence project, it will most likely include the inmate's initial letter requesting support. A private attorney, family member, or friend might include background information about the inmate's case. Regardless of who refers the case, intake personnel with the innocence project read the letter and, if the inmate is claiming actual innocence, will send a detailed questionnaire to the inmate for completion. The questionnaires are quite similar across the United States and typically seek detailed information about the crime for which the petitioner was convicted, his or her reason for claiming actual innocence, the time remaining on the sentence, information regarding all previous legal counsel and all previous appeals, and a waiver that enables the project to procure documents and speak to case-related people on the petitioner's behalf. In

addition, projects request all appellate documents. Once the completed questionnaire and appellate documents are returned to the project, the case is assigned to a student investigator to review. Most cases are rejected at this point in the process (a) for failing to demonstrate that there is a viable claim of actual innocence, (b) because the time remaining on the petitioner's sentence is less than the time it would take to investigate and process a PCR, and (c) due to the perception that there is no way to establish actual innocence (e.g., evidence was destroyed or mishandled or there was no physical evidence).

The students' assessment of the merits of the case is presented at a case-staffing meeting before the project staff and other student investigators. If a decision is made to continue with the case, that is, if the staff is convinced that by virtue of a review of the questionnaire and appellate documents that there is enough doubt about the conviction to continue with the investigation, a follow-up letter will be sent to the petitioner requesting the entire case file. This will include the complete trial transcripts, all police reports, and forensic documents. In short, the innocence project students will receive everything known about the case that was included as part of the written record. Once these materials have been received by the innocence project, the case is assigned to a team of innocence project student investigators. These students will proceed to developing a complete case outline that summarizes key timelines, names, locations, and events. This information is presented to project staff and students for deliberation about ways to proceed with the case investigation. Students are responsible for knowing their cases inside and out. They will be the experts on the case. They will be the ones who must speak with police officers, witnesses, attorneys, and forensic analysts to find out as much as possible about what happened with the case, and whether there is any evidence that the petitioner was wrongfully or unlawfully convicted.

If there is physical evidence available to test, or some other kind of newly discovered evidence or constitutional violation that can be identified for presentation to the court on appeal, briefs will be filed on the petitioner's behalf by the attorneys and students associated with the innocence projects.

Remedies for Wrongful and Unlawful Conviction

Innocence projects not only have committed their time and energy to case investigation, but have also pushed for federal and state-level reforms that will minimize the likelihood of wrongful and unlawful conviction. Nationally, the Innocence Network has created the Innocence Policy Network to work on both state and federal reforms. The Innocence Policy Network played a crucial role in the policy introduction and lobbying efforts that led to passage of the 2004 Justice For All Act that provides for the right to petition for DNA testing, evidence preservation, better training and compensation for death penalty attorneys, increased compensation for wrongfully convicted federal inmates, and funding for independent investigations of state police crime labs. Innocence commissions charged with postmortem review of exoneration cases in order to recommend changes to crime scene investigation and due process have been established in North Carolina, Pennsylvania, Virginia, Illinois, California, Connecticut, and Wisconsin. Barry Scheck and Peter Neufeld have noted that all but eight states have laws allowing postconviction DNA testing, and almost half have provisions for preserving evidence for future analysis. Many jurisdictions have altered other policies dealing with eyewitness identifications and the recording of interrogations.

Innocence projects signify manifestation of a new civil rights movement. By virtue of their existence, across the United States nearly 400 innocent men and women have been freed from prison since 1989. The substantial changes to crime scene investigation, witness and suspect interviewing techniques, crime lab procedures, and improved indigent defense policies have been essential to the projects' success. At bottom, innocence projects are the "canary in the coal mine," revealing serious institutional problems associated with the way criminal cases in the United States are prosecuted.

INTERNATIONAL CRIME VICTIMIZATION SURVEY (ICVS)

The International Crime Victimization Survey (ICVS) provides worldwide data on crime victimization, allowing for cross-country comparisons. It comprises standardized sample surveys conducted in several countries. The ICVS was first used in 1989, then repeated in 1992, in 1996, in 2000, and in 2005. The number of countries involved has substantially increased over time, with many countries in Europe, Asia, Latin America, and Africa participating (often with face-to-face samples limited to capital cities). Thus, ICVS has grown to become *the* relevant worldwide source on crime victimization, reporting to the police, and attitudes toward the police, courts, and punishment. Since 1996, the questionnaire has regularly included questions on corruption (bribery) of officials, thus providing a valuable alternative source to the well-known Transparency International index. This entry discusses the background of international crime surveys, the obstacles associated with an international survey, the results and controversies associated with the first multicountry survey, and the future directions of the ICVS.

Background

The first crime surveys used outside the United States were conducted in Zurich, Switzerland; in Stuttgart, Germany; and in the Netherlands. All of these early examples of this American “export” were conducted in 1973. Whereas the Zurich and Stuttgart surveys were joint initiatives of Marshall B. Clinard (University of Wisconsin) and Günther Kaiser (Max Planck Institute of International Criminal Law at Freiburg, Germany) and designed to provide figures that were comparable with the pre-National Crime Survey city surveys, the Dutch survey by J. P. S. Fiselier was a national initiative and ultimately became a permanent survey under the responsibility of the Dutch Statistical Office beginning in 1983. Beyond the Netherlands, national surveys were conducted in England and Wales (beginning in 1981) and in Switzerland (beginning in 1984). Sporadically, surveys were conducted in other European countries, sometimes at the national level, but mostly at city level. Outside of Europe, early crime victimization surveys were conducted in Canada and in Australia.

These surveys, with the exception of the 1973 surveys in Stuttgart and Zurich, were not designed for international comparisons. Richard Block tried to assemble data from some of these surveys in order to compare crime rates and other relevant variables across countries. It turned out, however, that this attempt faced considerable shortcomings due to differences in interview methods, offense definitions, reference periods, and other features of survey methodology. As an alternative, Clinard and J. Junger-Tas proposed to use surveys specifically for purposes of international comparisons. Unlike statistics that by necessity will forever be linked to national offense definitions and processing procedures, survey data could be collected, these authors suggested, through strictly standardized interview methods using identical offense definitions and reference periods.

Obstacles to an International Survey

There remained, however, several practical obstacles to such an international survey, including the development of interview methods that made cost-effective as well as tightly standardized interview methods feasible. The chance to create such an endeavor came through the emergence of computer-assisted

telephone interviews (CATI). Starting in the early 1980s, this method became available on a larger scale in Switzerland, due to that country's extremely high telephone penetration rate. Thus, the first Swiss crime surveys of 1984 and 1987 were conducted through CATI by Martin Killias and his team at the University of Lausanne. Although one interview lasted, on average, about 30 minutes, the costs were less than 15% of face-to-face interviews. The results of re-interviewing face-to-face a subsample of seriously victimized respondents showed the high validity of CATI, disconfirming several reservations based on early tests of conventional (i.e., pre-CATI) telephone interviews in the United States. Further, CATI allowed the asking of a large number of questions to a small proportion of respondents through unusually complex questionnaires with many filters. Mail surveys that also were used at that time, even in comparative studies, faced far more limitations in this regard, as did face-to-face surveys where even well-trained interviewers reach limits in handling complex filters. Crime victimization surveys collect much "trivial" information (e.g., on lifestyle, leisure-time activities, and the possession of vehicles). Disclosing such details does not require much thinking on the part of the respondent and thus does not justify the investment required for a personal encounter.

There was, in addition, a further difficulty faced by all European crime victimization surveys up to that point: The surveys were vulnerable to "telescoping" (i.e., the reporting of victimizations experienced before the adopted reference period, which was usually one year preceding the interview). Early American pilot studies, such as those summarized in the volume edited by Wesley Skogan, revealed that many incidents are forgotten after a couple of months, a fact that led to the adoption of the "bounding" design. With this design, the same respondents are re-interviewed every 6 months and the interviewer is aware of the victimizations a respondent reported during the preceding interview. In Europe, this extremely cost-intensive method has never been adopted. The Dutch and the Swiss crime surveys adopted a different approach, namely asking the respondent first whether he or she had experienced the victimization during the last 5 years (or *ever*), and, if so, when the incident had happened. This design has the following advantages: (1) respondents regularly

devote a lot of attention to temporal and/or geographic limitations if the "when" and "where" questions are kept out of screening questions with quasi-legal definitions; (2) any respondent who may feel frustrated when learning that his or her victimization, although very serious, is not relevant in the context of the survey because it occurred shortly before the reference period, has an opportunity to tell the interviewer his or her full story; (3) even if the focus is on a shorter period, collecting data on serious offenses over a longer period is helpful because it increases the absolute number of such cases to more reasonable levels—a fact that is particularly important if, as happens mostly outside the United States, samples are not particularly large; (4) having data over a period exceeding 12 months is critical if the way the victim's case was handled by the police, insurance companies, victim support schemes, prosecutors, and courts is being measured.

First Multicountry Survey

The experience with CATI in Switzerland circulated within a Council of Europe committee on the position and rights of victims in the criminal procedure. Jan van Dijk, who directed the Dutch Ministry of Justice Research and Documentation Center, formed a working group in 1988 to discuss the feasibility of an international crime victimization survey. This working group opted for CATI, primarily because it allows a tighter standardization of data collection than any other method—a critical advantage in international surveys. The group further adopted a reference period of 5 years, with a follow-up question asking the respondent to locate the (last) incident more precisely in space and time (with special interest in the last year). There is no doubt, however, that the low costs of CATI interviews were critical when Europe's governments were approached, through the Dutch Ministry of Justice, to join by funding their national samples. For 1,000 or 2,000 interviews (i.e., the standard sample sizes proposed), the budget was affordable for 11 European countries, the United States, Canada, and Australia. For most of these countries, it was the first crime victimization survey ever conducted. The fieldwork was carried out during spring of 1989, and key results were published by van Dijk, Patricia Mayhew, and Martin Killias in 1990.

Controversies

The results of this first truly multicountry crime survey in criminology were controversial from the beginning, particularly in the Netherlands, where crime was higher than in most other European countries. Criticisms centered on the validity of CATI, the 5-year reference period, and a few offense definitions. Over the following years, these criticisms were addressed in several experimental tests. For example, Annette Scherpenzeel found identical victimization rates on two Dutch samples, interviewed through either CATI or “telepanel” (i.e., an early form of electronic questionnaires). Randomized experiments by Helmut Kury in Bochum and Erfurt, Germany, confirmed that victimization rates do not differ across interview method. The conclusion was more mixed, however, with respect to questions on attitudes (toward the police, punishment, etc.), where Kury observed some social desirability bias.

Scherpenzeel’s experiment included a test of the two reference periods. The results showed that a straight 12-month reference period (often used in crime surveys) produced, for burglary and robbery, rates 2.5 and 2.2 times those obtained with the ICVS format (where respondents are first asked about incidents experienced over 5 years, before a more precise indication of the time of occurrence is required). More recent experiments regarding surveys on self-reported delinquency (such as in Sonia Lucia and her colleagues’ 2007 article, “How Important Are Interview Methods and Questionnaire Designs in Research on Self-Reported Juvenile Delinquency?”) confirmed that telescoping former incidents into the 12-month reference period is a severe and largely underestimated threat to the validity of survey estimates, particularly in countries with low crime rates, such as Japan. Some newly developed surveys, such as the national crime victimization surveys in Sweden, ignore this experimental evidence and persist in asking respondents about events experienced “over the last year.” Even more surprising, the British Crime Survey has never considered experimentally testing its 12-month reference period, and it has expanded its sample to 40,000 respondents. Clearly, it is more difficult to control this problem in surveys than in face-to-face interviews where interviewers can devote more attention to geographic and temporal mapping.

Another controversy associated with the ICVS is that it has never included questions on the ethnic identity of victims and offenders, nor on certain explanatory variables (e.g., low performance of governmental services as a source of corruption). Despite all these controversies, the basic methodology has been adopted in other major international surveys, such as the first international survey on violence against women, which was coordinated by Holly Johnson, Natalia Ollus, and Sami Nevala.

Future Directions

At present, it is uncertain whether the European Union (through EUROSTAT) is going to conduct an independent survey, and, if so, how that will affect the ICVS. Challenges to CATI will come from the increasing popularity of cell phones and the decreasing number of households with fixed phones. A combined approach that, as the first choice, uses Internet questionnaires and, in a second stage, interviews nonrespondents through CATI, face-to-face, or mail questionnaires might be a suitable solution. After all, several experiments have shown that interview methods are far less important than the way questions are asked. Pragmatic solutions may, therefore, be best for keeping this unique data collection initiative alive.

INTERNATIONAL VIOLENCE AGAINST WOMEN SURVEY (IVAWS)

The past two decades have seen rapid growth both in the number of population-based surveys interviewing women about their experiences of male violence and in the sophistication of the methods used. To date, targeted surveys designed to assess the extent and nature of women's experiences of violence have been conducted in at least 70 countries

worldwide. Random sample survey data are preferable to police statistics or records of hospitals or other services, because the majority of assaulted women do not use criminal justice or social services and therefore are not counted in official statistics.

There is growing interest among policy makers and researchers in comparing levels of male violence against women, the consequences of this violence for women and their children, and common explanatory factors at the international level. Internationally comparative data have the potential to make several important contributions, including investigating universal or cross-cultural traits associated with male violence against women; assisting with the implementation of international agreements and norms; assisting participating countries in better understanding the dimensions and contexts of the violence in order to better target aid efforts; planning interventions and services; raising public awareness and debate; implementing legislative change; and, developing research skills and technical expertise at the local level. These activities can be the impetus for social change on a broader scale than is possible with national-level surveys.

Building on lessons learned in conducting national-level surveys in a number of countries, there have been three major initiatives to improve the comparability of statistical data on this topic at the international level. Two have as a primary focus the impact of violence on health: the Demographic and Health Surveys (DHS), which is conducted with the support of MACRO International and the U.S. Agency for International Development, and the Multi-country Study on Women's Health and Violence Against Women which is coordinated through the World Health Organization. A third is the International Violence Against Women Survey (IVAWS), which was developed to respond to the need for internationally comparative data on the prevalence and effects of male violence against women and victims' interactions with the criminal justice system. This entry explores the methodology and challenges of the IVAWS and the potential for surveys of this nature to contribute to international efforts to combat violence against women.

Methodology

The IVAWS has so far been fielded in 11 countries and comparative analysis has been conducted with

9 of those countries. Participating countries and the sample sizes in each country are Australia (6,677), Costa Rica (908), Czech Republic (1,980), Denmark (3,589), Greece (interviewing continuing), Hong Kong (1,297), Italy (25,000), Mozambique (2,015), Philippines (2,602), Poland (2,009), and Switzerland (1,973).

Greece and Italy were not included in the international comparative analysis because their surveys were underway at the time of writing. Each participating country was responsible for fundraising, and in most countries funding was obtained from government sources or some other national fund (e.g., in Mozambique, the survey was co-funded by three United Nations agencies). The selection of countries to participate in the IVAWS was thus in large part determined by the success of individual countries' fundraising efforts.

A mix of telephone and face-to-face interviewing was used. In Australia, Denmark, Hong Kong, Italy, and Switzerland, interviews were conducted over the telephone; in the remaining countries, face-to-face interviews were conducted. Decisions about the mode of interviewing were left to project coordinators in each country and depended on practical matters such as telephone coverage, the budget, and the type of sampling frame available in each country (e.g., households versus banks of working telephone numbers).

The key to ensuring comparability among surveys fielded in different countries is to develop and maintain a standardized approach throughout all components of the project. Thus a standardized questionnaire was developed for the IVAWS through collaboration with project coordinators and field tested in 13 countries. The questionnaire was prepared in English and project coordinators arranged for translation, first into the language of their country then back into English as a way of verifying the accuracy of the translation. Training for project coordinators was centralized, and each project coordinator was provided with a data capture system and a comprehensive manual outlining all steps of the survey methodology. Included in the manual are guidelines regarding budgeting, the skill sets required to form a research team, the technical facilities required for capturing and processing data, the recruitment and training of interviewers, sampling procedures to ensure random selection of respondents, and administering the questionnaire

in order to minimize errors, as well as instructions on coding, entering, and validating the data.

A range of ethical considerations must be taken into account when interviewing women on sensitive topics such as intimate partner violence and sexual assault. Training for project coordinators for the IVAWS emphasized the importance of following strict ethical guidelines at all stages of the project. These include protecting confidentiality, ensuring the safety of respondents, careful selection and specialized training and support for interviewers, reducing distress to participants and interviewers, responding to distress by referring respondents to available local services and sources of support, and helping to ensure that research findings are properly interpreted and used to advance policy and interventions.

An important end result of the IVAWS is the transfer of technical expertise and research skills to some countries where none might have existed previously. In such countries, where there is little reliable information on the extent of men's violence against women, participation in the IVAWS can also serve as a basis for raising public awareness, debate, and national and local action. In countries where there have been prior prevalence surveys on violence against women, the IVAWS offers the possibility of international comparisons. International comparative research, like the IVAWS, facilitates comparability among countries and cultures and is an essential component to finding international as well as local remedies and responses to violence against women.

Measuring Violence Against Women

Research has shown that surveys that use specific behavioral measures of a range of types of violent acts will produce more reliable and valid estimates than surveys that employ general all-encompassing terms such as *violence* or *assault*. This is because individual respondents can hold different ideas of what constitutes violence or assault and may be reluctant to include assaults by acquaintances, family members, and intimate partners if not questioned about them in particular. The prevalence of physical violence is estimated on the IVAWS through the following items:

1. Threatened to hurt you physically in a way that frightened you
2. Threw something at you or hit you with something that hurt or frightened you
3. Pushed or grabbed you or twisted your arm or pulled your hair in a way that hurt or frightened you
4. Slapped, kicked, bit or hit you with a fist
5. Tried to strangle or suffocate you, burn or scald you on purpose
6. Used or threatened to use a knife or gun on you
7. Physically violent toward you in a way not already mentioned

The prevalence of sexual violence is measured through the following items:

1. Forced you into sexual intercourse by threatening you, holding you down, or hurting you in some way
2. Attempted to force you into sexual intercourse by threatening you, holding you down or hurting you in some way
3. Touched you sexually when you did not want him to in a way that was distressing to you
4. Forced or attempted to force you into sexual activity with someone else, including being forced to have sex for money or in exchange for goods
5. Sexually violent toward you in a way not already mentioned

Results of the IVAWS in nine countries show the following:

- In the majority of countries studied, between 35% and 60% of women experienced physical or sexual violence by a man since age 16.
- In most countries, between 22% and 40% of women have been physically or sexually assaulted by an intimate partner.
- Between 10% and 31% of women have been sexually assaulted by a man other than an intimate partner.

The IVAWS identified certain factors that are correlated with women's victimization. In multivariate

analysis, the following were found to be significant predictors of intimate partner violence:

- Male partners used emotionally abusive or controlling behaviors.
- Male partners were heavy drinkers.
- Male partners used violence toward others outside the home.
- Male partners were abused in childhood or witnessed their fathers' violence.
- Women were abused in childhood or witnessed their fathers' violence.

These findings suggest that appropriate policy responses aimed at reducing violence against women should include targeting social norms that equate masculinity with alcohol abuse, with the use of violence inside and outside the home, and with subordination and control of their female partners. Targeted interventions to prevent child abuse may have the effect of reducing violence against women if fewer women and men grow up affected by the long-term damaging effects of child abuse. Reducing intimate partner violence should have intergenerational benefits as well, by reducing the number of children who are witnesses to violence and who learn that violence is an acceptable way to solve problems in intimate relationships. Reducing public violence by men may have spill-over benefits by also reducing violence against their female partners, and vice versa.

Reporting to the Police

In all countries studied, it was found that less than one third of women who were assaulted by an intimate partner report the violence to the police, and in all but one the figure was less than 20%. Even in cases where the violence or threats of violence were so severe the women feared their lives were in danger, 40% or fewer women in all countries called on the criminal justice system for help.

Societal-level attitudes and a culture that views intimate partner violence as acceptable can be major obstacles to ensuring that women receive the help they need to end the violence. A minority of women in all countries considered intimate partner violence to constitute a crime. Victims were more likely to consider the violence to be wrong but not a crime, or just something that happens. But, even

among those who considered the violence to be a crime, less than 40% reported such violence to the police in all but one country. This suggests that women tend to take into account a broader range of considerations than their own personal safety and the criminal nature of these acts, and that they do not always see engagement with the criminal justice system as the most effective strategy for ending the violence. It also points to the need for criminal justice agencies to engage abused women and their advocates in a continuous process of reviewing and improving their policies, training, and interventions strategies.

Challenges of Internationally Comparative Survey Research

Internationally comparative survey research poses many challenges for researchers. In addition to the ethical and logistical challenges associated with interviewing on sensitive topics, cross-national research is influenced by other complexities. For example, there will be differences in the extent to which women are familiar and at ease with responding to surveys and describing their experiences to a stranger in the context of an interview. Differences in culture can affect attitudes toward women and violence, norms protecting family privacy, and ideals and practices of masculinity. Norms that prevent women from speaking out about violence may affect their willingness to name their experiences in terms employed by the survey. Norms that endorse the use of physical and sexual violence against women can be affected by the political context, including the presence of war and conflict, displacement of populations, availability of weapons, and widespread use of violence to solve social problems. There also will be variation in the meaning of physical or sexual assault for individual women depending on their past experience and social situation, and this is bound to exist to a greater extent in cross-national comparative studies where societal-level differences are greater. There are additional challenges in ensuring that translation of the questionnaire and other survey materials into a variety of languages does not affect the results, since certain concepts may not translate well or may be misinterpreted.

Although every effort was made to adhere to rigorous scientific principles in designing, testing,

and conducting the IVAWS, it is difficult to anticipate and control for all the complexities that can arise in cross-national research. While survey designers do their best to ensure that the questions are clear and unambiguous and that they are thoroughly tested on a diverse group of women, in the end respondents will perceive their experiences to fit into the survey categories or they will not. They will perceive some benefit in reporting their experiences and disclose them to interviewers, or they will perceive some risk and choose to keep them private. Because of the importance of the survey results for formulating policy and for public awareness of the breadth of the problem, researchers must continue to search for ways to improve cross-national research methodologies.

INTERNET FRAUD

Internet fraud includes a wide range of illegal behaviors in which various facets of the Internet play an integral role in the transmission of intentionally deceptive and/or false representations for personal or organizational gain. Acts of Internet fraud typically involve the transfer of currency, goods and services, or personal and intellectual property across this interconnected set of computers

via applications, including the World Wide Web, email, chat rooms, or software (e.g., online gaming). Rather than being perpetrated face-to-face, Internet fraud is usually perpetrated through lines of network communication that serve to spatially separate the offender from the victim. Since the use of computers or computer networks is an important locus of the illegal act, Internet fraud is considered a special subcategory of cybercrime.

The Nature of Internet Fraud

Most acts of Internet fraud involve the use of deception or false claims that serve to make the behaviors illegal under most circumstances. The legality of Internet fraud is also likely to vary across jurisdictions, especially transnationally. For example, Internet conduct or business dealings considered lawful in Barbados may be deemed illicit in the United States. Describing the nature of Internet fraud is largely a subjective endeavor and entirely contingent on both the circumstances of the crime and the jurisdiction under which the act takes place. Some of the most widely cited types of Internet fraud common to the United States include the following:

Advance fee scams. Offenders promise to disburse significant monetary payoffs to unsuspecting consumers who are to receive such funds after making advance payments of smaller sums of money to the offender. While any number of story lines may be used as a backdrop for an advance fee scam, money is essentially transferred or given to perpetrators under the false promise that they will compensate the consumer at a higher rate in the future. Included in these scams are job offers, inheritance offers, money offers, prize, sweepstakes, lottery offers, and sweetheart swindles.

Credit card fraud. Many Web sites often require consumers to share credit card information at a variety of locations on the Internet to obtain access to the sites' restricted content, or for the purchase of various goods and services. Offenders involved with these sites may then use transferred consumer credit card information for purposes other than those intended by the consumer.

Fake check scams. Offenders fraudulently claiming to be legitimate consumers may overpay

unsuspecting individuals with counterfeit checks for goods and services purchased. In turn, offenders will ask the seller to send or wire the overage amount back. The counterfeit check will then bounce, and the seller could potentially lose the product, purchase price of the product, and overage amount from the check as well.

Identity theft. Identity theft can be perpetrated in many ways, but it generally occurs when offenders obtain access to an unsuspecting individual's personal information and identification, via the Internet, with the intention of using it for personal or organizational gain.

Investment scams/Ponzi schemes. Consumers are lured by falsely advertised claims of little-to-no risk and large returns on particular investment opportunities. Once consumers pay to invest in these products or services, they may receive less than initially advertised or their funds may not have been used to actually invest in any product or service. Offenders may profit from initial investment dollars or may invest the funds for themselves, resulting in a future gains.

Multilevel marketing/pyramid schemes. Under the guise of a credible business model, consumers pay for the ability to distribute goods or services to the public by paying for distribution access to members of the scheme. Offenders may profit merely from signing unsuspecting consumers up as distributors, while never delivering on the promise of any goods or services.

Phishing scams. Offenders may mimic respectable sources via emails, Web sites, or advertisements asking unsuspecting persons to confirm or transfer personal information to the illegitimate location and then use the information later for fraudulent purposes.

Online sales or auction fraud. Offenders engage in the nondelivery of payment, merchandise, or services through online sales or auction Web sites (e.g., eBay) to consumers who lawfully sold, paid, or bartered for such goods or services. To date, online sales fraud, followed closely by auction fraud, is the most commonly cited type of Internet fraud.

Travell/vacation fraud. Consumers are promised a particular set of amenities or accommodations upon payment, but receive lower-quality services or receive numerous hidden charges at the time of travel or vacation.

Extent and Cost of Internet Fraud

Conservative estimates place the number of Internet users in the United States at well over a hundred million adults, a figure that will likely continue upward. As the number of Internet users across the entire globe continues to rise, the amount of Internet fraud is likely to increase as well. Anyone who sends information across the Internet is susceptible to Internet fraud. Unlike conventional criminal acts that often result because of the convergence of offenders and victims in time and space, Internet crimes involve temporally and spatially separated offenders and the potential for victimization is always present.

Each year, as part of a collective effort of the Federal Bureau of Investigation and National White Collar Crime Center, the Internet Crime Complaint Center releases an annual report detailing the amount and scope of Internet fraud perpetrated against U.S. citizens. According to results from the 2008 report, Internet fraud complaints jumped nearly 30% from 2007 to 2008. Moreover, almost a third of all offenses reported through Internet fraud complaints in 2008 had to do with the nondelivery of merchandise or payment, while nearly a quarter of complaints concerned Internet auction fraud (e.g., eBay). Both crime categories contributed to substantial growth in the number of filed Internet fraud complaints, up from just over 200,000 grievances in 2007 to more than 275,000 for the 2008 calendar year.

Despite mounting rates of Internet fraud complaints, it is likely the full extent of Internet fraud committed each year is vastly underestimated. This may in part be due to underreporting of fraudulent Internet activities. Underreporting is associated with the nature of the Internet itself and with individuals' uncertainty about where to turn concerning charges of Internet fraud.

While the dollar costs associated with Internet fraud were estimated by the Internet Crime Complaint Center report to exceed \$260 million for 2008, it is possible the estimated cost figures

have also been heavily influenced by the underreporting of fraudulent Internet activities. The actual costs associated with Internet fraud are likely far greater than even the best estimates available.

Prevention of Internet Fraud

Because Internet fraud can take many different forms, prevention strategies are situationally contingent on the operating environment of both the offender and the victim. Unlike the situational environment for conventional crimes, Internet crimes present a particular set of problems, specifically with regard to the location of crimes, namely, cyberspace. Situational crime prevention methods, those that recognize and address opportunities specific to Internet fraud, present users with a viable fraud prevention strategy.

In an effort to prevent and combat Internet fraud, the Internet Crime Complaint Center provides local, state, and federal law enforcement and regulatory agencies in the United States with information contained in Internet criminal complaints to assist their investigations, make the public more aware of the growing Internet crime problem, and reduce victimization through Internet fraud. Beyond existing U.S. laws and regulations, the existence of an organized set of preventive regulatory and enforcement strategies has been elusive where Internet crimes are concerned. Law enforcement and regulatory agencies have not been provided with adequate resources or the technology training required to effectively combat the growing Internet crime problem. Consequently, little collaboration exists among agencies, as agencies are ill equipped to confront Internet fraud and adapt to the changing landscape of cybercrime.

From the perspective of the individual, several situational crime prevention strategies may be helpful in reducing, while not altogether eliminating, the risks associated with Internet use. Specifically, strategies that involve increasing the difficulty of perpetrating an Internet crime, decreasing the benefits and rewards of an offender's engaging in an act, and helping individuals make themselves less attractive targets may be considered the only practical solutions. These may be partially accomplished through the use of firewalls and antispyware/antivirus programs, as well as by educating individuals to be extremely cautious

with how and with whom they share personal information when using the Internet.

INTIMATE PARTNER VIOLENCE

Generally speaking, intimate partner violence (IPV) occurs when an individual in an intimate relationship intentionally harms the other person in the relationship. In the 1960s and 1970s, intimate partner violence was increasingly recognized as a problem across the world. Attention from researchers first surfaced when domestic violence advocates called attention to the plight of women victimized by their partners or spouses. Advocates pointed out that victims were being treated poorly by criminal justice officials, and few services were available to help victims of partner violence. Victimologists began to focus on domestic violence to help advance the area of study beyond the discipline's traditional victim precipitation orientation. The issue quickly moved from being an issue that no one talked

about to being recognized as a social problem warranting significant attention from researchers, policy makers, academics, practitioners, and advocates.

Since that time, many have accepted that intimate partner violence is a problem that needs to be addressed by different disciplines and practitioners. Most agree that the best response to intimate partner violence involves what is called a “multidisciplinary” or “integrated” response. This means that several different agencies are involved in the preventing and responding to intimate partner violence. Indeed, intimate partner violence is no longer viewed as a family problem that should remain hidden within the confines of victims' homes; rather, intimate partner violence is now regarded as a global public health problem. Fully understanding the integrated response required to address intimate partner violence involves knowledge of the following areas: the types of intimate partner violence, the extent of the violence, the dynamics and patterns surrounding such violence, and the causes of intimate partner violence.

Types

Intimate partner violence is typically categorized as one of three varieties: (1) physical assault, (2) sexual assault, or (3) psychological assault. Physical assaults include a range of behaviors (hitting, kicking, biting, stabbing, shooting, pushing, grabbing, shoving, and so on) that have the potential to result in bodily injury to the victim. Sexual assaults include rape and noncontact offenses such as voyeurism and forced exhibitionism. Psychological assault includes a range of behaviors in which offenders use verbal or psychological tactics to harm their partners.

Extent

After a review of studies conducted across the world, reporter Sheila Hotchkin concluded that worldwide one in three women have been victims of violence. Similar estimates have been found in the United States. The National Violence Against Women Survey, jointly funded by the National Institute of Justice and the Centers for Disease Control and Prevention, is among the most

comprehensive studies focusing on issues related to intimate partner violence. Led by investigators Patricia Tjaden and Nancy Thoennes, this project involved phone surveys with 8,000 women and 8,000 men. Respondents were asked about their experiences with different forms of violence, including rape, physical assault, and stalking/harassment. The findings of this national survey related the following:

- 7.7% of women reported being raped by an intimate partner
- 22.1% of women were physically assaulted in their lifetime, and 1.3 million reported being physically assaulted in the preceding 12 months.
- 5% of women reported being stalked in their lifetime, and more than 500,000 reported being stalked in the preceding 12 months

Some researchers have argued that intimate partner violence against men is just as pervasive, if not more pervasive, than intimate partner violence against women. Results of a few studies have shown that a high number of men have been abused by their partners. Critics of these studies point to three problems that call into question the utility of the body of research showing males have higher rates of intimate partner violence. First, many of the studies finding higher rates of intimate partner violence victimization among males have used Murray Strauss's Conflict Tactics Scale. This scale has been criticized for failing to consider the context surrounding victimization and measuring acts that are not universally defined as violence. Second, critics have suggested that violence by women against men is often for self-defense in response to violent actions initiated by an aggressive male partner. Third, critics point out that violence by women is typically of a relatively minor form, at least in comparison to violence by men against women. Simply put, sheer physical strength differences mean that men do more physical harm to women than women do to men. This is not to suggest that intimate partner violence against men is not an issue. Certainly a number of men are victimized and they warrant appropriate services; however, the vast majority of serious intimate partner violence cases appear to be instances where men abuse women.

Dynamics and Patterns

Researchers have devoted a great deal of effort to understanding the dynamics and patterns surrounding intimate partner violence. This research has been useful in generating a description of the nature of intimate partner violence. Patterns and dynamics that have been uncovered are listed below and described in the paragraphs that follow. They include the following:

- The chronic nature of intimate partner violence
- The cycle of violence
- The duration of intimate partner violence
- The battered woman syndrome
- The characteristics of batterers

The *chronic nature of intimate partner violence* has been demonstrated by the National Survey of Violence Against Women, which found that more than half of women sexually assaulted by their partners, and two thirds of those physically assaulted by their partners, were victimized by their partners on multiple occasions. Clearly, intimate partner violence is typically not a one-time incident. Further, in *Policing Domestic Violence*, Lawrence Sherman supports these findings. He argued that a vast majority of domestic violence incidents are committed by a small number of offenders.

Another pattern surrounding intimate partner violence is the *cycle of violence*. This concept recognizes that intimate partner violence does not happen every single day of a victim's life. Originally created by Lenore Walker, the cycle of violence explanation suggests that violence is part of a cycle involving a series of stages. First, during the honeymoon phase, the abusers treat their partners as if they are newlyweds. Gifts, promises of a lifetime of commitment, and romantic displays of affection are frequent. Second, during the tension-building phase, the relationship transitions to one in which angst and disagreements become more frequent. Third, the battering episode stage occurs when the abuser acts out aggressively against the victim. This is followed by the honeymoon phase, during which the abuser "makes up" for his harmful actions.

A related pattern has to do with the *duration of intimate partner violence*. Generally, these actions occur over time. Because of the offender's ability to convince victims that the abuse will stop, victims

are sometimes reluctant to leave their abuser. Of course, it is not just the abuser's "charm" that keeps victims in violent relationships. Often, others will ask, "Why doesn't she leave?" when they think of intimate partner violence incidents. Four responses to this question are worth nothing. First, rather than asking, "Why doesn't she leave?" one could ask, "Why doesn't *he* leave?" Why is it that the woman should be expected to be the one to leave? After all, the abuser is ultimately responsible for the abuse. Expecting the victim to leave inadvertently places responsibility on the victim rather than the abuser.

Second, in considering the patterns surrounding leaving domestic violence relationships, an oft-quoted saying from domestic violence advocates comes to mind: "Leaving is a process, not an event." Intimate partner violence victims do leave their abusive relationships. It just takes time for them to leave. A commonly cited estimate suggests that women leave abusive relationships for good after being physically abused between seven and eight times.

Third, some researchers have suggested that asking "why" women don't leave violent relationships holds very little utility in terms of broadening our understanding about intimate partner violence. In their 2005 book *Family Violence and Criminal Justice*, criminologists Brian K. Payne and Randy R. Gainey noted that it is more appropriate to ask *how* women stay in abusive relationships than *why* they stay.

Fourth, domestic violence victims stay in violent relationships for a number of reasons that help to explain why leaving these relationships is so difficult. The National Coalition Against Domestic Violence cites barriers such as lack of resources, institutional responses, and traditional ideologies as making it difficult for victims to leave violent relationships. Lack of resources can be an enormous obstacle to leaving an abusive partner, as victimized women typically do not have the resources required to leave and create a new household on their own. Many intimate partner violence victims have at least one dependent child, and obtaining the financial resources they need to take care of their children can be virtually impossible on their own. Because of the dynamics of control in their intimate relationship, many of these women may not hold jobs.

In addition, the responses of institutions designed to protect women from harm may inadvertently contribute to continued violence. Police officers may not be aware of strategies to help victims or services available. They may actually tell victims that they should simply stay in their relationship and make up with their partner. Helping professionals—like social services professionals, clergy, and counselors—may fail to recognize the abuse. Even when they see it, they may be unaware of effective ways to help women in these relationships.

Traditional ideology also keeps women in abusive relationships. Many battered women grew up in families where their fathers abused their mothers. They are socialized to believe in marriage at all costs. Women may rationalize the abuser's actions as part of a typical marriage, or they may convince themselves that the abuse is not that serious.

Cultural factors may also keep women in these relationships. For some individuals from different cultures, intimate partner violence is something that cannot be disclosed to any outside sources. Describing this phenomenon, the Family Violence Prevention Fund noted that battered immigrant women experience many barriers to leaving abusive relationships. Overriding cultural values from the woman's home culture may conflict with American values, creating conflict between adhering to different sets of values.

Related to the fact that intimate partner violence is often chronic, experts recognize that *battered woman syndrome* is a consequence of this violence for some women. The psychological effects of intimate partner violence can be devastating for victims. The combination of the psychological effects, according to domestic violence expert Lenore Walker in her classic work *The Battered Woman Syndrome*, has the capacity to lead to the syndrome, which is a type of posttraumatic stress disorder. According to Walker, the syndrome is produced by trauma due to repeated experiences of different forms of domestic violence. The foundation of the syndrome includes (1) the flight response and (2) cognitive impairments from the abuse. This syndrome, which is also termed *battering and its effects*, is well accepted in the medical field and in disciplines such as psychology, social work, and counseling. It is sometimes used as a legal defense in murder cases in which women explain their homicides against their abusers by suggesting that their years

of abuse caused them to fear for their lives and act out violently toward their abusers.

Another pattern or dynamic in intimate partner violence has to do with the characteristics of batterers. Indeed, to fully understand the dynamics surrounding intimate partner violence, it is imperative that one has understanding about batterers. According to the Centers for Disease Control and Prevention, three types of batterers exist. These include the following:

- The *family only batterer*, who may perpetrate less severe violence, use relatively little psychological or sexual abuse, and display few or no symptoms of psychopathology
- The *dysphoric/borderline batterer*, who may perpetrate moderate to severe violence, mostly confined to the family, and may be generally distressed, dysphoric, or emotionally volatile
- The *generally violent/antisocial batterer*, who may engage in moderate to severe intimate partner violence and, of the three types of batterers, the most extrafamilial violence; the batterer also may have the most extensive history of criminal involvement, alcohol, and drug abuse, as well as antisocial personality disorder or psychopathology

National organizations have provided guidance in further understanding the characteristics of batterers. The American Bar Association, for example, has provided the following characteristics of batterers:

- Batterers discourage victims from getting help.
- Batterers frequently insist on accompanying victims everywhere.
- Batterers harass, stalk, and keep tabs on their victims.
- Batterers isolate victims from their friends, family, and acquaintances.
- Batterers keep victims from working.

Note that each of these characteristics makes it more difficult to leave violent relationships. Also providing insight into the characteristics of batterers, the National Coalition Against Domestic Violence noted that batterers (1) objectify women; (2) have low self-esteem, feel powerless and inadequate, and externalize the causes of their behavior; (3) may be pleasant and charming between

violent incidents; and (4) exhibit warning signs such as jealousy, possessiveness, bad tempers, unpredictability, cruelty to animals, and verbal abusiveness.

Causes

Researchers have devoted a great deal of effort to identifying the causes of intimate partner violence. In line with victim precipitation research by victimologists, early explanations focused on how victim characteristics and behaviors contributed to IPV. Criminological theory was noticeably absent from many early explanations of this type of violence. Payne and Gainey have argued that to fully explain intimate partner violence, it is necessary to consider the characteristics and behaviors of offenders rather than victims. They further suggest that traditional criminological theories have some utility in explaining intimate partner violence.

In applying criminological theory to IPV, one can see how the source of this violence can be similar to the source of other forms of harmful behavior. Routine activities theory, for example, can be used to explain intimate partner violence. Abusers are the motivated offenders, victims are the vulnerable targets, and the fact that much of the violence occurs behind closed doors is equivalent to the absence of capable guardians. Social disorganization theory can also be applied to intimate partner violence, as living in disadvantaged areas can exacerbate the risk, and consequences, of this type of violence. And conflict theory can be used to explain the woeful response of criminal justice officials to intimate partner violence. The lack of penalties given to offenders for this violence is consistent with the ideas of deterrence theory. In addition, the consistent finding that intimate partner violence is learned from family members is in line with differential association theory. The list could go on and on. The main point is that criminological theory can be used to explain IPV.

Power and control explanations are the most commonly cited explanations of intimate partner violence. The basic assumption underlying power and control explanations is that abusers use violence to control their partners. The power and control wheel has been used to illustrate the ties between power and control. This wheel was developed by the Domestic Abuse Intervention Project,

which was created in Duluth, Minnesota, in 1980. After police began arresting all domestic abusers in Duluth, offenders were given the choice of a 6-month treatment program instead of jail. During the program, facilitators recognized that offenders were describing a series of nonphysical behaviors they performed in order to control their partners. Facilitators of the treatment program categorized the kinds of comments offenders made about controlling their victims into the power and control wheel. After describing their wheel with abusers, the facilitators recognized that abusers increased their nonphysical behaviors when they were unable to physically abuse their partners as part of their desire to control them.

The power and control wheel identified several activities that are performed in order to maintain control. First, offenders use intimidation through tactics such as glances, property destruction, and speaking loudly. Second, offenders use emotional abuse through actions such as verbal abuse and emotional neglect. Third, abusers use isolation as a strategy to make their victim more dependent on them (and thus less likely to leave). Fourth, offenders minimize and deny their behaviors by suggesting to their victim that they are really doing nothing wrong in their relationship. Fifth, offenders use their children to maintain power and control by making their victim fear for her children's safety. Sixth, offenders use male privilege by invoking patriarchal rules in the household and making important decisions without their partner's input. Seventh, abusers use economic abuse by controlling the finances and not allowing their partners access to financial resources. Eighth, offenders use coercion and threats to get victims to comply. Offenders might, for example, threaten to kill their partner, their children, or themselves as a strategy to get their victims to do certain things. The similarity between these tactics is simple: offenders, wanting power, do things to control their victims. This is the underlying assumption of power and control theory.

INTIMATE PARTNER VIOLENCE, RISK ASSESSMENT

The science of risk assessment in intimate partner violence (IPV) is relatively new. As research has increased in the field generally, so has demand for demonstrated accuracy in predicting risk in domestic violence cases and for the use of IPV risk assessment in criminal justice, advocacy services, and health care settings. As the science of IPV risk assessment has developed over the past decade, so have the identification of risk factors, for both re-assault and intimate partner homicide or near homicide, and the realization that the risk factors for the two outcomes, although overlapping, are not exactly the same and do not operate at the same degree of risk. In this entry, the term *risk assessment* will be used for assessing the risk of IPV re-assault or recidivism, while the term *lethality assessment* will be used for assessing the risk of an intimate partner homicide or near homicide.

The most commonly used methods for assessing both re-assault and lethality that have been validated in prospective studies in peer-review journal publications are described along with a brief summary of the evidence. The entry ends with recommendations for the use of these methods of risk assessment in a systemwide process.

Risk Assessment Instruments

The three most widely used risk of re-assault instruments are the SARA (Spousal Assault Risk Assessment), the ODARA (Ontario Domestic Assault Risk Assessment), and the DVSI-R (the revised Domestic Violence Screening Instrument). The oldest and most validated IPV risk assessment instrument is the Spousal Assault Risk Assessment, or SARA, which was developed in Canada by Randy Kropp and Stephen Hare as a structured professional judgment guideline intended to assist professionals to come to a judgment of the level of risk of re-assault in cases of IPV. It was primarily intended for use in the criminal justice system and is widely used in probation departments, but it is also used in domestic violence advocacy. Its shorter version, the B-Safer (Brief Spousal Assault Form for the Evaluation of Risk), has not been separately validated but was based on extensive data testing the SARA. The ASAP (Aid for Safety Assessment Planning) incorporates both the SARA and the B-Safer to guide in risk evaluation and safety planning with victims.

The Ontario Domestic Assault Risk Assessment, or ODARA, developed in Canada by Zoe Hilton, was designed for frontline police officers, but it can be used by victim services, health care workers, probation, and correctional services personnel. The ODARA was developed based on Ontario domestic violence arrest data. In subsequent testing with a new data set, also from the Ontario domestic violence criminal justice database, the ODARA achieved an area of .77 under the ROC (receiver operator curve). The area under the ROC reflects the percentage of cases captured under a curve that combines the sensitivity (true positives or cases where recidivism was predicted and occurred) and specificity (cases where no re-assault was predicted and none occurred) across the range of risk scores on an instrument. The receiver operator curve area ranges from 0 to 1.0, where 1.0

represents perfect accuracy. ROC analysis is an appropriate strategy to use to assess the predictive accuracy of a risk assessment instrument.

The Domestic Violence Screening Instrument, or DVSI, developed by Kirk Williams, contains 11 items (and thus is almost as short as the ODARA, which contains 13 items), and it is user-friendly for criminal justice systems, with the information needed for all items available from the police incident files. The DVSI was independently tested in a prospective study of victims of IPV in New York City and Los Angeles (known as the Risk Assessment Validation Experiment, or RAVE study) achieving an area under the ROC of .60. Subsequently, it has been revised (and called DVSI-R) and tested prospectively in a large study in Colorado with an area under the ROC of .71. The DVSI-R is used widely in probation departments in Colorado, Connecticut, and other U.S. jurisdictions.

Lethality and Severe Re-Assault Assessment

DV-MOSAIC, developed by Gavin de Becker and his associates in 2001, is a computerized threat assessment system based on intimate partner homicide data. DV-MOSAIC is longer than the DVSI-R and ODARA, and the only assessment instrument that incorporates protective as well as risk factors. It was developed for use in police departments and by domestic violence criminal justice specialists using data gathered from an investigation of the case. Levels of risk are determined through the programmed algorithm easily communicated to victims from a printout of the level of risk and its meaning. DV-MOSAIC was independently tested in the RAVE study, with 65% of the cases of severe re-assault accurately assessed with ROC curve analysis.

The Danger Assessment (DA) was developed based on IPV homicide data from three published studies, and extensive case and group work with women in shelters, in order to help abused victims determine their level of danger of homicide or near lethal attack. It consists of a calendar assessment filled out with victims that helps them see for themselves the actual pattern of IPV, followed by 15 yes/no items formulated in wording that abused women can understand. Data from a recent case control study of homicide were used to formulate a weighting scoring system and levels. They were

subsequently tested on a sample of attempted homicide victims with a receiver operator curve of .90. In the RAVE study, the DA achieved a .69 under the ROC for severe re-assault.

Victims' Assessment of Risk

In the RAVE study, victims' perception of risk accurately captured 61% of "any re-assault" and "severe re-assault," adjusting for the protective actions that put the victim out of possible physical contact from the perpetrator (e.g., the victim going to a shelter or the perpetrator being in jail). This was a greater proportion of accurate prediction than that made by the DVSI (not DVSI-R) and DV-MOSAIC, but smaller than the Danger Assessment. Other examinations of the accuracy of victim perception of re-assault have found that abused women are good predictors of re-assault but are more likely to underestimate than overestimate their risk. The D. Alex Heckert and Edward Gondolf prospective study of abusers in batterer intervention programs and their victims found that the combination of the original 15-item DA combined with victims' perception of risk was the most accurate of the instruments used in assessing risk of re-assault.

Use in Systemwide Process

There have been at least three reviews of DV re-assault and lethality risk assessment approaches, several published investigations of predictive validity of specific instruments, one comparison of the SARA and the DA, and an experimental test to comparatively evaluate four of the methods plus victims' perceptions of risk in the same sample (the RAVE study). This demonstrates that there is beginning to be a body of knowledge that allows choice of an instrument or system based on its predictive accuracy as well as on its utility in a setting and intended use.

Thus, there is sufficient evidence of accuracy to use the methods summarized above and to end the usage of lists without validation. In a recent meta-analysis examining clinical judgment against statistical judgments in 92 studies, statistical methods were found to be more accurate than other methods overall. In the case of domestic violence, victims' perceptions of risk also have a place, but

victims often underestimate their risk of re-assault, and especially of lethality. Therefore, validated statistical assessment of potential re-assault and lethality needs to be part of the overall coordinated response to domestic violence, and used as the basis for safety planning for and by abused women and community strategies to keep women safe.

INTIMATE PARTNER VIOLENCE, THEORIES OF

Intimate partner violence occurs in an environment of complex, often interrelated issues, including individual, situational, psychological and couple relationship factors, in the context of a social, political, and economic environment. There are many different theories of intimate partner violence, which concentrate on explaining clusters of issues. These theories can be categorized in many different ways; some describe intimate partner violence in terms of intra- or interpersonal factors that affect the couple dynamic, and others use models which include structural or institutional elements that foster the use of violence in the wider society.

Intrapersonal theories are drawn from the discipline of psychology and encompass a range of personal pathologies, including physiological and mental instabilities and related inability to control emotional outbursts. Examples might be the roles of obsessive ideation, paranoia, disassociation from feelings, substance use or an acquired brain injury in the perpetrator that leads to poor impulse control; in addition, a flawed attachment experience during childhood can lead to hypersensitivity in which any feelings of hurt, fear, or jealousy are immediately transformed into anger. Low self-esteem, depression, and anxiety can trigger both perpetration and victimization. This group of theories also includes discussions of reinforcing behaviors that can be associated with intimate partner violence, such as watching violent movies, using pornography, possessing weapons, and a history of criminal activity.

The range of theories categorized as *interpersonal theories* focus on the dynamic between the couple in the relationship. The Duluth Domestic Violence Project made important contributions to theory by illustrating how control is enforced using psychological and emotional means in addition to violence through the processes described by the *power and control* and *cycle of violence* models. In 2000, Michael Johnson and Kathleen Ferraro theorized that there were two distinct types of intimate partner violence. The power and control dynamic plays little part in the *common couple violence* where either partner may lash out, whereas in *intimate terrorism* the violence is motivated by control. *Exchange theory* explains the calculated use of violent behavior in achieving the perpetrator's goals, while *investment theories* look at the level of commitment in the relationship to explain intimate partner violence.

Structural theories show how social and economic inequalities translate into aggression and violence. *Feminist theories* regard intimate partner violence as the result of a patriarchal society where male coercive power and domination over females is promoted and reinforced. For example, a belief in the rights of a male to chastise and punish his partner, along with a general endorsement of the use of aggression and violence by men in the exercise of power and control in the wider social system. In *resource theory*, power within an intimate relationship is based on the command of resources, whether economic, psychological, or social. When resources are scarce or threatened, aggressive behavior and violence are tactics used to increase control. For example, a man who perceives that he has lost control in an intimate relationship is likely to use violence to restore his power.

Social situation/stress and coping theory provides a two-dimensional explanation as to why intimate partner violence may occur in some situations and not others. The first dimension is the position of the dyad in the social structure (e.g., employment and income levels), and the second dimension is the capacity of the dyad to deal with stress and includes the coping strategies that may be used by either partner. One or both partners may resort to violence to deal with episodes of financial strain in a society where the use of violence is seen as an appropriate response to stress.

Social learning theory explains how the use of violent behavior is transmitted between generations. For example, Debra Kalmuss found that repetitive exposure to violence in the emotionally loaded environment of the family predisposed children to use violence, and adult victims of intimate partner violence were six times more likely than others to have been subjected to violence as children. However, the explanation offered by social learning theory is only partial, as research into the pathways to violent behavior has found that not all children exposed to violence become perpetrators or victims.

Murray Straus first applied *general systems theory* to intimate partner violence in 1973, where the system involved individuals, their behaviors and pathologies, and family backgrounds as well as the social spheres, cultural influences, and organization of the society in which they live. General systems theory describes the processes that characterize the use, management, and stabilization of violence in family interactions.

Donald Dutton proposed an *ecological theory* that integrates many of the above theories of abuse and applies to both victims and perpetrators. The ecosystem of a violent relationship has a foundation layer that is based on intrapersonal psychological factors, followed by a family system layer in which the individual experiences such negative actions as abandonment, neglect, and abuse. The next layer contains peer group issues such as education, religious training, alcohol and drug use, and gender role socialization. The final layer describes the influence of wider sociopolitical gender inequalities, media portrayal of subjugation

and violence against women, and racial/ethnic/cultural prejudices. *Life path* theories also take into account the changes in personal and environmental effects over time.

The heterogeneous nature of intimate partner violence makes it problematic for a single theory to take into account all the dynamic and static elements that produce violent acts between intimate partners, such as social conditions, social policy, political events, and shifts in social history that are taking place as well as the situational, individual psychological, and couple relationship factors.

JOURNEY TO CRIME

Journey to crime (JTC) is one of the better-researched aspects of crime in the crime and space literature. Research on JTC attempts to understand how offenders' movements in space factor into the discovery of unintended targets, leading to crimes of opportunity; into offenses planned by serious criminals taking steps toward known targets; and into purposive hunting patterns in areas thought to be target rich. Clearly, understanding the JTC process more completely would provide the police with a set of tools with which to effectively track down active offenders and lead to tremendous benefits for crime prevention and reduction efforts. Three core aspects of this literature deal with determining (1) the point of origin (or anchor) for a particular crime or set of crimes, (2) the directionality of the crime trip, and (3) the actual distance traveled between nodes. Like economic geography research, which has long studied the characteristics of consumers deciding on where to locate retail outlets (catchment areas, for example), JTC research studies the characteristics of offenders deciding on where to journey "to work" (that is, commit crime). Journey to crime research, although similar in many ways to criminal profiling, should not be confused with it. Whereas journey to crime research is applied to the specific journey (and chain of events and decisions) undertaken by an individual offender leading up to a specific crime, criminal profiling seeks to work back from a set

of crime event locations that are thought to be linked in some way in an effort to estimate possible nodes of activity that the offenders may use, such as residences.

Point of Origin and Direction of Travel

"Home" is often used as starting point in JTC research, but it is widely understood that crime trips do not have to start from a residence; they can begin in any central node of activity. As JTC research only considers crimes for which travel was needed, "zero-distance" crimes such as domestic assaults or the production of illegal narcotics or substances in an offender's home are usually not part of a formal JTC analysis, as the origin and endpoint are the same.

Once a point of origin is determined (such as through an examination of police records of convicted offenders), the crime trips can be measured for associated crime sites and areas or locations the suspect is known to frequent. Directional bias, or the tendency for trips from anchor points to a given set of destinations to be clustered in something approaching a mean cardinal direction, helps researchers to determine likely travel paths. Specific types of locations have been shown to have attractor and/or generator properties for crime events, and thus knowing offenders' direction (if not literal paths) will assist both active and "cold case" analyses. Directionality also helps investigators look for additional clues, information, suspects, or any potential, as-yet-undiscovered nodes of activity.

Distance Traveled

Opportunity-based crimes tend to involve the least amount of precrime preparation and occur closest to nodes used during routine activities. According to the least energy (or least effort) principle, equally suitable targets that are closer to the potential offender are preferable to those further away. This principle also suggests that at some point, the potential offender would experience a diminishing return for travel and effort expended and expected/realized reward from the crime.

Research findings on trip distances by crime type show that more spontaneous and affective crime types, such as domestic assault, involve the shortest distances. Data from the mid-1970s, for example, show distances to rape of approximately 1 mile as a modal measure, burglaries at just over one mile, and robberies at approximately 1.5 miles. These findings are not consistent, but nevertheless, all of these distances are relatively short. For example, a 2007 Finnish study reported average travel distances for burglars as being approximately 2.4 miles (or just under 4 kilometers). Thus, affective or emotionally charged crimes involve shorter distances than do instrumental crimes. Presumably the latter involve a specific target, such as a certain store or warehouse that is known to have a particularly lucrative “haul” of goods, and this may be seen as deserving some additional effort, planning, and travel than other, more immediate targets. This is borne out in research on serial arsonists, for whom any suitable target will do, and who therefore have no need to seek out special targets. Australian research, for example, finds that young offenders set most fires with little motive beyond immediate gratification in the form of excitement or entertainment. This is at least partly why distances traveled for this type of crime are typically among the shortest—often less than half of a mile. This changes when fire settings involve instrumental purposes. These more purposive crimes are more likely to include specific targets to which the offender must travel. Keeping with fire setting as an example, arson for revenge (or for fraud) may call on the offender to travel several miles to attack a former boss or place of employment. Here, the crime is a means to an end, rather than the end itself.

Of course, not all targets are equal, so some level of decision making takes place, but the majority of

empirical evidence suggests that most crime trips are undertaken by offenders who traveled relatively short distances, and that as much as four fifths (80%) of all crime occurs as a result of opportunities discovered in the course of routine, noncriminal activities. Burglar interviews and analysis of solved offenses using police incident data show that burglars tend to find (and act on) targets closer to their point of origin rather than those further away, and that they avoid targets close to home. This “buffer zone” of reduced offending quickly fades, however, as the offender moves toward his or her destination. The buffer zone effect, which was first described by Paul and Patricia Brantingham in *Patterns in Crime*, is theorized as being primarily a strategic response on the part of offenders to avoid recognition if they are seen in a potentially compromising set of circumstances. However, not all researchers agree on the existence of the buffer zone. Recent work in Chicago involving police incident data from the late 1990s involving violent altercations showed no such buffer around offenders’ home locations, although the researchers found that travel distances were, nevertheless, short (and conformed with expectations arising from routine activities theory, which are described in the entry on the theory in this encyclopedia).

Measurement

Several measurement options are available to JTC researchers, but only two basic forms are discussed here. A Euclidian, or straight line, distance between start and end locations is the simplest distance measurement between two points. This “as the crow flies” distance is easy to calculate, but reflects rather poorly the paths of (and distances traveled by) people in the built environment. To capture more realistic estimates of trips between points in an urban setting, researchers often use the “Manhattan” metric, which estimates the likely distance traveled as the sum of the distances needed to move along two lines that form a triangle, assuming the original, straight path distance forms the hypotenuse.

Actual distance traveled is only part of a JTC analysis. Most people consider the time spent in transit at least as, if not more, important. Simple distance measures, then, need to be adapted to include such “costs” as time spent in transit,

among other things (e.g., convenience), and of course the actual monetary costs involved. Such considerations are highly subjective and not always accurately estimated, leading to inefficient travel patterns that “make sense” to the traveler because they are the most comfortable, even when more efficient paths are available. Of course, the mode of travel figures prominently in any travel distance–time estimation. Clearly, people are apt to be less concerned about literal distance traveled than the time spent traveling when they are driving to work every day. Most would drive a bit farther than strictly necessary if it enabled them to cut their travel time.

To improve JTC modeling, researchers often modify expected travel distances by including the impact of a range of additional variables, such as mode of travel, traveler demographics, urban infrastructure (areas known for goods and services, road networks, foot/bicycle pathways, etc.), and topographical features (e.g., bodies of water and bridges).

City planning efforts have an obvious impact on people’s daily routines, and consequently, opportunities for licit and illicit activities alike. Certain city zones, such as entertainment districts with bars or nightclubs as major services, are known to attract problems. Knowing something of key areas and locations assists in forecasting likely nodes that serve as points of contact during the journey to—and from—crime. Kim Rossmo’s *Geographic Profiling* is one of the most accessible introductions to—the specific methods of analytical work on offender movements, including JTC and the prediction of key nodes where complete travel information is not known. Gravity models are used by geographers to predict the movement of people in space based on some supply-and-demand assumptions, such as the availability of a particular class of goods or services. For example, consumers will undertake a certain amount of effort to find suitable goods, but will eventually stop spending energy and take the best deal that they can find. Such estimations provide the “distance decay functions” (i.e., diminishment of actions as distance traveled increases) included in most research on the journey to crime.

Simulation

JTC research involves both retrospective accounts of known offenders and simulation studies. In

retrospective studies, actual paths can be more or less accurately reproduced for a set of offenses. Such examples assist greatly in the calibration of techniques to predict missing information when examining incomplete cases. Given the interest in predicting trip distances, and estimating the start points where points of origin are not known, it is not surprising that simulation work is flourishing. A detailed discussion of simulation methods is not possible here, but key work in this area includes joining geographic information systems (GISs) and agent-based systems modeling. Although there is considerable variation in the types of simulation research in this area, generally, such efforts place a hypothetical offender (agent) into a network of travel options, such as a digitally reproduced road network (or “graph”), and then specify potential targets and start and end points. The simulation then allows the agent to make several hundred “trips” to see what paths and targets are “found” by the agent, and of those, which are actually used and acted on. Simulation models provide an arena in which it is possible to test theory about relatively rare events, such as homicide, as well as to assist in crime prevention and reduction efforts of investigators by supplying a more efficient strategy for resource (surveillance, evidence searches, etc.) deployment in the field. This contribution is subtle but vitally important to the growth of offender movement theory, as it provides a new path for empirical findings to feed back into theory. Finally, simulation studies build on the set of computational approaches—along with geographic information systems techniques—to build on what is becoming more widely referred to as “crime science.”

JUVENILE OFFENDING AND VICTIMIZATION

Substantial research investigating offending and victimization has found that they may be intertwined. High rates of victimization and offending exist among juvenile populations, and studies have made clear that these categories are not mutually exclusive. Most of the research has focused on one or the other of these phenomena, however, rather than the relationship between delinquency and victimization.

The Victim–Offender Connection

The connection between juvenile offending and victimization has been established. What is less clear is *how* victimization and offending are linked. That is, does offending result in victimization, or does victimization lead to offending? And, are these relationships reciprocal, or are there other factors that explain both offending and victimization?

There is strong support for the idea that participation in delinquency is related to an elevated risk of victimization. Many victims of violence have histories of serious delinquency. Victimization

also appears to be a risk factor for offending, especially for committing violent offenses. Thus, there is some evidence that the relationship between offending and victimization is not unidirectional. It appears that violent offending affects victimization, and violent victimization is related to an increased risk of later victimization and violent offending. Since there appears to be some relationship between victimization and offending, it may not be surprising to find that similar factors may account for both juvenile offending and victimization. Factors such as self-control, family and peer influences, gang fights, drug selling, and carrying a weapon are examples.

Theories

In describing the relationship that exists between offending and victimization, several explanations have emerged. One line of thought suggests that offenders are more likely to be in situations that would result in an increased risk of victimization. This contention is supported by findings that those involved in the most serious delinquency had higher rates of violent victimizations. It is also important to note, however, that many offenders are not victims of crime, nor are all victims offenders.

The primary explanation utilized and supported to clarify this relationship is that in lifestyle theory and routine activities theory. Michael Hindelang and his colleagues developed lifestyle theory to explain differences in victimization. The basic premise of this theory is that victimization occurs due to an individual's lifestyle or associations. In this sense, lifestyles that are characterized as deviant and risky can contribute to offending and victimization in similar ways. A situation that is conducive to offending is also characterized by elements related to victimization. Since these two concepts are invariably linked together—offending does not exist without victimization—those surrounded by delinquency based on their lifestyle may be at higher risk of victimization either in the context of offending or as a result of retaliation or retribution.

Lawrence Cohen and Marcus Felson further developed this area of theory by introducing routine activities theory. This proposition states that when three things—(1) motivated offenders, (2) suitable targets, and (3) lack of capable guardians—converge in time and space, victimization

will occur. Thus, participating in delinquency increases the risk of victimization by decreasing the number of guardians or by increasing exposure to motivated offenders. Some individuals, for example, may have more contact with offenders due to their environment, while others may have more contact with offenders because of their activities.

According to these theories, increased victimization results from several factors related to delinquency. First, increased exposure to offenders can result in higher rates of victimization. Those involved in delinquency, for example, often have greater exposure to both delinquent situations and individuals that can result in increased victimization. Second, the nature of offending can affect victimization because situations that are conducive to crime are also conducive to victimization. For instance, prostitutes in the process of committing a crime also expose themselves to situations in which they could become a victim. Third, offenders make extremely suitable victims. Offenders are more likely not to report crimes committed against them, as they try to avoid police detection for their own crimes. In addition, offenders may be less likely to report victimization due to the perception that they are less likely to be believed or have their victimization taken seriously by law enforcement and/or their losses are illegal contraband that would bring additional police scrutiny of their own activities.

Related to these explanations are victim precipitation theory and subcultural theory. Victim precipitation theory proposes that victims encourage victimization by their own behavior. The relationship with offending is most often associated with what is classified as active precipitation. For example, in the case of a barroom brawl, one individual begins a fight by insulting another, but miscalculates the ability of the target and comes out on the losing end. Thus, through their actions, offenders become victims. In addition, subcultural theory states that certain groups possess norms that require a reaction to disputes, such as retaliation,

that turn offenders into victims during the course of the response.

K

KIDNAPPING

Under the common law, kidnapping was defined as the unlawful confinement and transportation of a person out of the country. Originally it was a misdemeanor, but kidnapping is now statutorily defined in all jurisdictions in America and is considered a serious felony.

Kidnapping, as a crime, was brought to national attention in America when the baby of famous aviator Charles Lindbergh was kidnapped and murdered in 1932. In response to the extensive public outcry, Congress enacted the Federal Kidnapping Act (also known as the Lindbergh Law) in 1934, which provided the death penalty for kidnapping that results in death.

The Law

Although every jurisdiction's criminal laws are different, as a general rule, each one recognizes the crime of kidnapping. Most of the kidnapping laws in America contain the following elements: (1) a person's knowingly or intentionally (2) transporting another person (known as *asportation*) (3) against his or her will, (4) by force or threat of force, and (5) restraining, holding, or confining that person for a certain amount of time. Some kidnapping laws have a requirement of secrecy. Many kidnapping laws include additional elements, such as the purpose of the kidnapping (e.g., ransom, sexual assault, or hostage taking) and whether it was committed in conjunction with

another crime (e.g., robbery). The penalty for crimes that include these elements is usually higher. Many jurisdictions have a lesser degree of punishment where the kidnapping involves family members such as children.

Kidnapping differs from false imprisonment, which was recognized under the common law as a crime and is usually defined as having the following basic elements: (1) a person's knowingly or intentionally (2) unlawfully restraining another person, (3) substantially interfering with that person's liberty. The primary difference between the crimes of kidnapping and false imprisonment is the transportation of the victim. Another term often used in place of false imprisonment is *hostage taking*. Hostage taking and kidnapping are similar, but they are often defined in different statutes.

Understanding the Crime

Kidnapping can be divided into several general types. These include (1) political, (2) sexual, (3) financial, (4) domestic, (5) psychological, (6) slavery, and (7) hostage-associated kidnappings. Of course, there is some overlap between the different types. Political kidnappings usually involve the taking of a high-profile person, occasionally a diplomat or government official, to compel a government to take some action such as the release of political prisoners. These kidnappings also are a favorite tool of terrorists, who frequently use them to obtain operating funds. Sexual kidnappings usually involve situations where the perpetrator takes the victim to a remote place for sexual

assault. Financial kidnappings are usually done to extort money from a wealthy person or corporation. Executives from large corporations and children of wealthy families are the usual victims in these kidnappings. Domestic kidnappings usually involve the taking of a child where there is an ongoing dispute over custody in a divorce or separation. It should be noted that, as a general rule, if there is no court decree or restraining order in effect, it is generally not considered kidnapping if one parent takes sole possession of the children. Psychologically based kidnappings are usually associated with serial killers, who kidnap their victims and then take them to remote places and kill them. Such kidnappings share some features with sexual kidnappings, but their purpose is not sexual and involves other factors, such as revenge, ritualistic crimes, or a psychological disease. Slavery-related kidnappings involve people, usually women, being taken and held against their will and forced to work, usually in menial occupations or as sex slaves. Finally, hostage-associated kidnappings are usually committed in conjunction with other crimes. For example, if a robbery is interrupted, the perpetrators may take hostages with them to attempt to ensure their escape.

One of the most widespread problems concerning kidnapping is the issue of custody of the children where the parents are separated or divorced and custody is in dispute. Several authorities estimate that more than 300,000 children are kidnapped every year. To prevent domestic kidnapping, a number of laws have been enacted. The Parental Kidnapping Prevention Act of 1980, for example, a federal law that applies to the states, discourages interstate kidnapping of such children by preventing jurisdictional conflicts when children are taken across state lines (Public Law 96-611, 94 Stat. 3568 [1980]). Further, the Uniform Child Custody Jurisdiction Act and its successor, the Uniform Child Custody Jurisdiction and Enforcement Act, one or both of which have been adopted by all the states in various forms, allow for continuing jurisdiction for custody in the home or resident state of the child.

One of the problems with analyzing the prevalence and prevention of kidnapping is that it is not listed as a Part I offense by the FBI's Uniform Crime Reporting Program. This has made it difficult to obtain a complete understanding of the incidence

and characteristics of the crime. There have been a number of calls to rectify this problem.

Prevention

Prevention of kidnapping is difficult, given the nature of America as an open society. However, corporations and wealthy people employ security personnel to prevent financial kidnappings, and governments usually have elaborate protection systems for their diplomats and officials to prevent political kidnappings. Domestic kidnappings are extremely difficult to prevent, given that usually both parents are allowed direct access to the children, and court decrees and restraining orders are not always effective tools of prevention. The AMBER Alert system has helped solve and/or terminate these child kidnappings. (For more information on this system, see the entry "AMBER Alert" in this encyclopedia.) Prevention of sexual kidnappings, at least when the victim does not know of a potential perpetrator, are usually best prevented by cautious practices in dating and travel.

KIRKHOLT BURGLARY PREVENTION PROJECT

The Kirkholt area of Rochdale, which is one of the former mill towns common across Lancashire,

England, and is now part of Greater Manchester, is a public housing estate comprising some 2,300 homes. It is historically a challenging area in terms of both reputation and recorded crime. In the early 1980s it was singled out by Greater Manchester Police as the location within their force area with the most acute domestic burglary problem. Funding was put in place to study and reduce the incidence of that offense. A police officer, David Forrester, was assigned to the project, under the supervision of researchers Mike Chatterton and Ken Pease. The report of the first phase of the project was published as *The Kirkholt Burglary Prevention Project, Rochdale*.

Overview

When police records dealing with Kirkholt were scrutinized, it was found that they lacked the detail necessary to inform target hardening (such as clarity about burglars' method of entry), so an ambitious interview program was undertaken. Interviews with local burglars, victims, and other residents confirmed that target hardening should be the police's initial tactic of choice. Lacking funding to target harden over 2,000 dwellings, the police decided that their first step should be to identify the most vulnerable homes for priority attention.

At the time, the police perception of residents of the Kirkholt estate was that they were largely less than upright citizens, but Forrester returned from the interviews infused with a sense of the essential decency of most of the residents—and a burning desire to help those who had been chronically victimized by burglary. Contrary to expectations, it was found that prior burglary victimization was the best indicator of vulnerability to burglary in the future. In fact, the level of repeat burglary in the year before the implementation of the project was such that the majority of crimes were against households that already had been targeted at least once during that calendar year. Thus, putting the possibility of crimes being moved to another location to one side, the prevention of all repeat burglaries would result in the prevention of more than half of all domestic burglaries within a year. The alternatives (such as prioritizing single-parent households and the most victimized part of the estate) would be less efficient and more vulnerable to perceptions of unfairness. For instance, a householder whose

neighbor receives help that she herself does not might well be resentful, and a denizen of one part of Kirkholt who sees resources deployed elsewhere on the estate might be similarly unhappy. By contrast, it is unlikely that citizens would object to burglary victims' receiving help geared toward the prevention of their being burglarized again. In addition, target-hardening burgled and neighboring homes provides a steady (but, it is hoped, declining) workload for those engaged in target hardening the homes, whereas target hardening by demographics or area provides a one-time task for people who are then dismissed or allocated work elsewhere. The steadily declining workload was termed *drip-feeding* and is an often overlooked advantage of target hardening that occurs as a result of criminal events.

At its core, the Kirkholt project involved target hardening both burgled homes and neighboring homes. The inclusion of near neighbors' homes was based on the notion that capable guardianship could be exercised to prevent repeated burglaries, and that target hardening these homes would sensitize their occupants to the situation, causing them to exercise this guardianship. It also was based on the notion that neighbors may have been burglarizing each other, and the manifestation of a serious intent to remedy the burglary problem would be helpful in warning them off. Indeed, the preproject assumption of police in the area was that Kirkholt residents were faking their burglaries. Evidence that emerged in the study made it clear that this was a very minor part of what was happening. The invocation of neighbors to become capable guardians was termed *cocoon watch*, and it extended across Kirkholt to become the more conventional Neighborhood Watch scheme.

Results

The Kirkholt project reduced burglary on the Kirkholt estate immediately and dramatically. The number of domestic burglaries fell from 316 in 1986 to 147 in 1987—a decline that was not reflected in the rest of the police area. Further, repeat victimization showed an especially dramatic decline. Within practical limits, it was shown that crime had not been displaced by place (elsewhere in the area) or crime type. The improvement remained, and the evaluation ended in 1990. A

second report on the project by Forrester and his colleagues in 1990 is noteworthy for its early attempt at cost-benefit analysis, and for the observation that it was increasingly householders new to the area who fell victim to burglary. In the year before the project was implemented, 10% of the burglaries in Kirkholt were suffered by those living in the area for less than 2 years. In the third year of implementation, that figure had jumped to 49%. This is in part attributable to the improved reputation of the estate and its consequent increase in the number of occupied homes. Highlighting the vulnerability of newcomers to burglary was an important incidental finding of the study of Kirkholt.

Criticisms

The claimed success of the Kirkholt project came under criticism, no doubt because the success was so dramatic and replications were less successful (at least in part because they were not full replications). It was suggested that the burglary reduction was attributable to general estate improvements rather than target hardening. The Home Office commissioned David Farrington to review the evidence and reanalyze the data. His report (which was never published) indicated that the decline had tracked the target hardening of burglary victims rather than tracking other types of improvements. After more than 20 years, what are we to make of the Kirkholt project? The points worth remembering include the following:

1. Because the burglary rate in Kirkholt was extremely high before the project, one could anticipate a decline in burglary on the basis of the rate simply declining to a more normal level, independent of the intervention.
2. As the project contained a package of measures, it is impossible to tease out the components of its “active ingredient,” although some clues can be gathered from the shape of the reduction—for example, there was a greater reduction in burglaries in semidetached homes than in maisonettes (apartments on two floors), where the overall building design and environmental setting provided more crime opportunities.
3. One aspect of target hardening was the removal of the meters, sometimes called “burglars’

piggybanks,” into which residents in British public housing up to the 1980s typically inserted coins to prepay for their electricity. These meters, which were in a standard place within the home and easy to break into, often contained a substantial sum. Before the project, 49% of all burglaries involved loss of meter cash, and 27% nothing but meter cash. Thus the meters were the ultimate “low-hanging fruit” for target-hardening crime preventers.

4. In addition to the features that made the project a success beyond the reach of projects that followed it, the Kirkholt project had the distinction of being the first project that used what was known about how victimization is concentrated as the basis for the prioritization of crime reduction efforts.

5. The project “got lucky” in its deployment of cocoon watches, wherein target-hardening help was offered to near neighbors of burglary victims. Later research showed how burglary risk is communicated to near neighbors, but this was not understood at the time. The burglary reductions achieved by the project were greater than the total numbers of preproject repeats, and there were some postproject repeats, so the balance of the reduction came from somewhere else. It is plausible that it came from neighbors of burglary victims, but this was not measured at the time. It is now more productive to think of repeat victimization as a special case of communicated risk.

6. Despite its flaws, the Kirkholt project was an important step forward in placing the prevention of repeat victimization on the crime prevention agenda. And the concepts of drip-feeding and cocoon watch speak to practical crime reduction issues. However, crime concentration at the individual and household levels remains a ubiquitous feature of crime patterns, and an affront to notions of distributive justice. Thus the scope for prevention via the reduction of repeat victimization and other instances of communicated risk remains considerable in scale and worthy in terms of its fairness in spreading the burden of crime around.

L

LANDMARK VICTIM-RELATED COURT CASES, FEDERAL, UNITED STATES

The United States Supreme Court and the federal appellate courts have decided many landmark victim-related cases since the 1980s. In the U.S. legal system, laws have little practical meaning without judicial interpretation; therefore, case law is crucial to our understanding of the contours of victims' legal rights and remedies. Landmark victim-related cases are those that establish new legal principles or substantially change existing law and that have great significance to the evolution of the victims' rights movement. Historically, the goals of this movement have been to expand victims' participatory rights in the criminal process, to secure adequate restitution for victims, and to enact better crime control measures. These goals provide a useful framework for this discussion of landmark victim-related cases.

Participation in the Criminal Process

Victim Impact Evidence

The most recognized victim-related cases in the United States are the Supreme Court's decisions involving victim impact evidence (VIE) at sentencing. Although initially disinclined to permit VIE, the Court eventually granted victims the right to participate in capital sentencings. These cases mark

the Court's earliest recognition of the victims' rights movement.

In *Booth v. Maryland*, 482 U.S. 496 (1987), the Supreme Court held that consideration of VIE—evidence about victims and their family—at the penalty phase of a capital trial was unconstitutional. Because the jury's focus shifts from the defendant to the victim when presented with VIE, the decision to impose the death penalty could be arbitrary and capricious. Recognizing society's growing concern for victims' rights, the *Booth* dissenters urged deference to state legislatures' decisions to expand victims' role at sentencing.

The Supreme Court extended the holding of *Booth* in *South Carolina v. Gathers*, 490 U.S. 805 (1989), to bar VIE from a prosecutor's argument to the jury. The Court held that the prosecutor's argument, in which he commented extensively on the victim's personal characteristics, impermissibly introduced sentencing factors unrelated to the defendant's blameworthiness. The dissenters in *Gathers* argued that jurors should know the human cost of the crime and called for *Booth* to be overruled.

The reconfigured Supreme Court did just that in *Payne v. Tennessee*, 501 U.S. 808 (1991). The Court held that consideration of VIE at capital sentencings is not unconstitutional. The opinion focused on the direct relationship between the degree of harm suffered by the victim's family and the defendant's punishment. The strong public support for victims' rights influenced the Court's decision. Irrespective of the rationale, *Payne* represented a paradigm shift in the Court's view of victims' rights.

Enforcement of Victims' Rights

Since *Payne*, federal and state legislation has greatly expanded crime victims' rights to participate in criminal cases. Even more significant, however, is the development of mechanisms for victims to enforce these rights.

Enforcement has not always been available to victims. For example, in *United States v. McVeigh*, 106 F.3d 325 (10th Cir. 1997), the district court entered an order prohibiting victim witnesses from attending the trial of Timothy McVeigh, one of the Oklahoma City bombers. The excluded victims appealed. The Tenth Circuit Court of Appeals held that it did not have jurisdiction to overturn the appeal because neither the relevant federal statute nor the Constitution granted the victims a legally protected interest in attending the trial. However, public outcry after the *McVeigh* holding prompted Congress to pass emergency legislation to allow the excluded victims to attend the trial, notwithstanding their intent to give VIE at sentencing.

Recent cases reflect legislative efforts to create enforcement mechanisms for victims and a shift in judicial interpretation of victims' statutory rights. In *Kenna v. United States District Court for the Central District of California*, 435 F.3d 1011 (9th Cir. 2006), the Ninth Circuit Court of Appeals reviewed a provision of the Crime Victims' Rights Act (CVRA). Victims of a multimillion-dollar fraud scheme gave VIE at one defendant's sentencing hearing, but the district court denied them the opportunity to speak again at the other defendant's hearing. On appeal, the *Kenna* Court interpreted the CVRA's right to be reasonably heard to mean the right to speak at every relevant sentencing hearing, not just the right to submit a single written statement. The Court endorsed the CVRA's aim to make victims full participants in the criminal trial process and to give victims equal footing with prosecutors and defendants.

The shift in favor of victims has come so far that, in *United States v. Perry*, 360 F.3d 519 (6th Cir. 2004), the Sixth Circuit Court of Appeals allowed a victim, although not a party to the criminal case, to appeal a restitution order. Until *Perry*, federal courts had found that the Constitution prevented victims from making such challenges.

These cases are significant. They demonstrate that Congress and the courts are responding to

public opinion in favor of the expansion of victims' rights. Although the issues of whether a victim has a legal interest in the criminal trial of a defendant and, if so, whether that interest should be enforceable, are still unsettled, the courts appear to be siding with victims.

Victims' Civil Remedies

The questions surrounding victims' legal interests are not limited to the context of criminal trials. Victims also seek civil remedies from defendants and from government entities that have failed to protect them. In contrast to lawsuits against offenders in state courts, victims' federal lawsuits must overcome certain constitutional barriers. Therefore, federal lawsuits have met with limited success.

Lawsuits Against Offenders

For example, when a campus rape victim sued her perpetrators under the Violence Against Women Act of 1994 (VAWA), the statute was struck down. Congress and victims' advocates had intended the VAWA civil rights statute to provide recourse beyond traditional state law remedies to victims of gender-based violence. The Supreme Court held in *United States v. Morrison*, 529 U.S. 598 (2000) that Congress lacked the necessary constitutional authority to enact that particular section of VAWA. Despite this ruling, several states enacted similar legislation, and victims continue to seek civil redress in state courts.

Lawsuits Against the U.S. Government

Victims have secured more rights in the criminal process over the course of the victims' rights movement, yet there has been no corresponding development in victims' lawsuits against governmental entities. The Supreme Court has held that the government generally has no constitutional duty to provide protection against privately inflicted harms or to enforce all laws.

In *DeShaney v. Winnebago County Department of Social Services*, 489 U.S. 189 (1989), the Department of Social Services failed to take action for over 2 years in a suspected child abuse case, which resulted in irreversible brain damage of the 4-year-old victim. The social service officials knew that his father posed

a risk of violence but failed to intervene. Nevertheless, because the child's injury occurred at the hands of a private party and the child was not in government custody, there was no constitutional violation.

The Supreme Court recently affirmed the *DeShaney* holding in *Town of Castle Rock, Colorado v. Gonzales*, 545 U.S. 748 (2005). Gonzales reported that her husband had taken their children in violation of a restraining order, but the police repeatedly refused to take action. Later that evening, Gonzales's husband murdered the children and was killed in a shoot-out with the police. The Court found that, despite its mandatory language, the state law did not give Gonzales entitlement to the enforcement of a restraining order because the police and prosecution had some discretion with respect to its enforcement.

In addition to finding that the government has no affirmative duty to protect victims from their offenders, the Supreme Court also has imposed constitutional barriers to federal causes of action. The Court has severely circumscribed crime victims' use of the Constitution as a remedy for the wrongful conduct of government entities and officers.

Crime Control Measures

In addition to imposing limits on victims' ability to secure civil remedies, the Supreme Court has sometimes hindered victims' push for greater crime control. Victims seek the enactment of laws that criminalize more behavior, enhance the severity of criminals' punishment, and provide victims with protections and reparations. The Court has invalidated such laws if they burden criminal defendants' constitutional rights.

Notoriety for Profit

The Supreme Court considered New York's "Son of Sam" law in *Simon & Schuster, Inc. v. Members of the New York State Crime Victims Board*, 502 U.S. 105 (1991). To prevent criminals from profiting from their crimes and to recompense victims, the law required an accused or convicted criminal's income from works depicting his crimes to be collected and distributed to the victims of the crime. The Supreme Court held the law unconstitutional because it imposed a financial burden on speakers solely because of the particular content of the speech. New York and other states

subsequently remedied the constitutional deficiencies in their Son of Sam laws.

Hate Crimes

Hate crime legislation seeks to criminalize behavior that is motivated by certain characteristics of the victim. The Supreme Court considered whether expressions of hate against victims, such as cross burning, can be prohibited and punished in *R.A.V. v. City of St. Paul, Minnesota*, 505 U.S. 377 (1992). The Court struck down an ordinance that prohibited hate speech based on race, color, creed, religion, and gender. The Court held that the government may not regulate speech on the basis of the government's hostility or favoritism toward the underlying message expressed.

However, in *Wisconsin v. Mitchell*, 508 U.S. 476 (1993), the Supreme Court upheld a sentencing statute that enhanced the penalty for a defendant convicted of a physical assault who intentionally selected his victim because of the person's race. The Court ruled that the statute did not violate the defendant's free speech rights by punishing his beliefs; the statute punished the bias motivation behind his conduct. The Court affirmed this principle in *Virginia v. Black*, 538 U.S. 343 (2003), in which it upheld a law banning cross burning so long as it required the state to prove that the defendant acted with the intent to intimidate the victim.

These cases epitomize the inherent conflict between victims' rights and defendants' rights. Hate crime legislation attempts to reconcile the two by regulating biased conduct against victims without censoring defendants' speech.

Sex Offender Registration and Notification

Victims' advocates pushed for the enactment of sex offender registration and notification laws to prevent against sexual victimization. Thus the Supreme Court recently considered the constitutionality of state versions of Megan's Law. The Court upheld the state laws in *Connecticut Department of Public Safety v. Doe*, 538 U.S. 1 (2003), and in *Smith v. Doe*, 538 U.S. 84 (2003), finding no constitutional infirmity with regulatory measures adopted for public safety reasons. These cases signal the Court's continued protection of victims; however, they do not end future challenges to these laws.

Future Outlook

Throughout these cases, the Supreme Court has explicitly acknowledged the need to provide victims with more rights and with enforceable remedies. The Court, however, has placed the onus on Congress and state legislatures to create a remedial system within constitutional boundaries. As public sentiment in favor of victims' rights continues to grow, we can expect a legislative and judicial expansion of victims' rights and remedies. Because such rights and remedies will likely conflict with defendants' rights and present constitutional questions, it is inevitable that the Supreme Court will revisit the issues presented in these landmark victim-related cases.

LANDMARK VICTIM-RELATED COURT CASES, INTERNATIONAL

Starting with the creation of the International Military Tribunals at Nuremberg and Tokyo in the aftermath of World War II, the international community set up various international criminal courts

over the course of the 20th century whose goal was to prosecute acts of particular gravity. Victims' rights before international courts, which were completely excluded from the proceedings in the early days of international justice, have considerably evolved in the last decade. After a brief presentation of the existing international criminal jurisdictions, this entry examines their definition of the victim and presents some important cases that have shaped the rights of the victims appearing before them.

International Criminal Tribunals

In 1993 and 1994 respectively, the United Nations established two international criminal tribunals to prosecute very serious violations of international humanitarian law committed in the former Yugoslavia since 1991 and in Rwanda during 1994. Under their rules of proceedings, victims have no autonomous role. They have no legal representatives, have no access to the files of the case, and cannot intervene except as witnesses (and only when asked to do so by the court, the prosecutor, or the defense). They cannot claim any compensation and only have a right to *restitution* (i.e., the return of any property acquired by criminal conduct to their rightful owners). However, a tribunal's guilty verdict can be used by the victim to claim compensation in his or her national jurisdiction. The reason for such a limited role for victims resides in the fact that it was thought at the time of the creation of the tribunals that the prosecution represented the interests of the victims as well as those of the international community. The Rome Statute (1998), however, recognizes that these interests may conflict and thus that victims need their own representatives.

Hybrid Tribunals

In addition to international tribunals, various hybrid criminal tribunals were set up between 2000 and 2007, namely the special courts for Bosnia-Herzegovina, Cambodia, East Timor, Lebanon, and Sierra Leone. Each has its own characteristics, but all are regulated by national as well as international law, are integrated into the national justice systems, and are financially supported by the international community. They all have jurisdiction

over massive violations of international criminal law as well as some serious offences of national criminal law, and they employ both international and national magistrates. Being implemented on national territory, where the crimes occurred, the tribunals are culturally and politically close to the victims. Nevertheless, victims' rights in the jurisdictions vary greatly, and though still unclear, the tribunals' provisions seem limited in that respect.

International Criminal Court

The situation is different before the International Criminal Court (ICC), which for the first time in international law grants autonomous rights to the victims. The ICC is an independent and permanent tribunal created and regulated by the Rome Statute, which was joined by 108 state members. It tries individuals prosecuted for crimes against humanity such as genocides and war crimes. The Rome Statute and the Rules of Procedure and Evidence (RPE) both contain provisions that allow the victim to participate in the criminal justice process, which requires that the victim first be defined.

Definition of the Victim

Rule 85 of the ICC RPE defines two types of victims. People are considered victims when they "have suffered harm as a result of the commission of any crime within the jurisdiction of the Court." Organizations and institutions, however, may have the status of victims if they have sustained "direct harm to any of their property which is dedicated to religion, education, art or science or charitable purposes and to their historic monuments, hospitals and other places and objects for humanitarian purposes."

This raises two questions: First, what is *harm*? Second, when does the status of victim take effect?

The definition of *harm* can be problematic: What degree of harm must a person have suffered to qualify as a victim and how direct must it be? As harm is not defined in the Rome Statute or in the RPE, it lies within the court's competence to define it on a case by case basis: physical harm, moral suffering, and material loss all constitute harm. It seems that the court will also consider indirect suffering. In a decision dated June 29, 2006, the court referred to the definition given by

the *United Nations Declaration of Basic Principles of Justice for Victims of Crime and Abuse of Power* in 1985, which includes suffering caused by the loss of a close relative while helping victims or trying to prevent victimization.

Then, as indicated in a decision by the Pre-Trial Chamber I, dated January 17, 2006, there must be a causal link between the harm suffered and a crime falling within the jurisdiction of the Court. This means that the alleged victim must be able to prove that he or she was victimized by the accused; hence the importance that the victim be allowed to participate in the proceedings at an early stage to help establish the identity of his or her aggressor. However, in the *Lubanga* case, the court ruled that, at the early stage of the trial, when a *situation* is investigated, it is sufficient for the victim to establish there are *grounds to believe* that he or she was victimized by the accused. Later, when a *case* is being tried, the victim must show there are reasonable grounds to believe that he or she was victimized by the accused during the crimes for which the accused is being tried by the court.

When does the status of victim take effect? In the decision of January 17, 2006, the court held that the right of the victims to participate starts as early as the investigation on the situation, that is, even before an arrest warrant or a summons to appear is issued.

Rights of Participation

How the provisions of the Rome Statute and the RPE regarding victims should be put into practice precisely is left to the court to determine. Victims have a right to participate at any stage of the proceedings, when *their interests are affected*. This is a flexible criterion, which will depend, among other elements, on the stage of the proceedings.

As stated in the decision of January 17, 2006, the rights of participation of the victims start at pretrial stage, when the court tries to determine whether there is a ground for prosecution. Victims must be informed if the court or the prosecutor decides not to proceed with an investigation. Their rights also include the right to attend the hearing, to present oral and written views and concerns, to present evidence, and to examine and cross-examine witnesses. They have a right to be informed of the requests and conclusions made by the other

parties, and of the progress of the proceedings. They also have a right to make observations when the jurisdiction of the court or the admissibility of an action is challenged. However, victims have no right to open an investigation.

Moreover, victims have a right to legal representation: Rule 90 of the RPE states that victims are free to choose a legal representative, which the court shall only limit if it is inappropriate in a specific case.

Victims may benefit from *protective measures*. In the *Lubanga* case, the Pre-Trial Chamber I held that the protection of victims, up to then restricted to victims “appearing before the Court,” should be extended to victim applicants, who must be protected from the time the court receives a completed application to participate in the trial. When appearing as witnesses, victims must be protected against reprisals from the offenders, but also from a possible revictimization caused by the trial itself. Their privacy must be protected, and the prosecutor can withhold any evidence that can gravely endanger a witness or a witness’s family. The court may derogate to the principle of public hearing and may allow evidence to be presented by electronic means, for example by allowing a witness to testify by video.

But there are limits as to how and when victims may participate: It is the court’s competence to decide in what form and when it is appropriate for victims to intervene (i.e., in a manner that is not prejudicial to the rights of the accused). They must apply in writing to the registrar (i.e., the principal administrative officer of the court) before being allowed to address a trial chamber. If there are numerous victims, they may be asked to choose one or more common representatives, unless there is a conflict of interests, in which case separate representation will be allowed. Victims’ legal representatives may only examine witnesses, experts, or the defendant once authorized to do so by the trial chamber, and may be requested to do it only in writing.

Rights of Reparation

The ICC is the first international jurisdiction to grant victims a right to reparation. As an individual right, it is independent from the right to participate. But the court can also order collective reparations, which shall benefit all the victims of a crime, including victims not represented during the

proceedings. Reparation can be granted to the victims themselves or to their families and dependents.

The ICC statute provides for three forms of reparations, namely, restitution, compensation, and rehabilitation. *Restitution* aims at restoring victims to the situation that was theirs prior to the crime; this includes the restitution of their property and employment as well as their return to their place of residence. *Compensation* is reparation for the damage suffered; it is a substitute for restitution, and can be awarded for medical expenses, loss of earnings, and compensation for physical and mental sufferings. *Rehabilitation* includes psychological and medical care, as well as social and legal assistance. It aims at alleviating the consequences of the crime. However, the list is not exhaustive. For example, the court can request guarantees of nonrepetition or order public apologies, or that a judgment be publicized. The court may ask states to proceed to seizures of property and assets against individuals for the restitution to victims, and states are required to comply with such orders. Yet, the court cannot issue reparation orders against states themselves.

To help the court determine the appropriate compensation, it can appoint experts to help establish loss, injury, and damage. The Rome Statute also establishes a trust fund for victims, which benefits crime victims within the jurisdiction of the court and their families. This serves two goals: providing reparation to the victims when the court makes awards to victims through the fund and managing voluntary contributions to the benefit of larger groups of victims who may not have suffered directly from the crimes within the jurisdiction of the Court.

What is not known yet is at what stage of the trial the victim can apply to obtain them: Must the victim wait until the accused is pronounced guilty, or are reparations due as soon as the victim has proved him- or herself a victim? What about victims who join trial after the guilty verdict? The principles governing reparations are still uncertain and will be established by the court, as prescribed by Article 75 of the Rome Statute.

The Victims and Witnesses Unit

Besides allowing for the participation and reparation of the victims, the court, through the Victims

and Witnesses Unit, also provides counseling and protection for the victims, the witnesses, and their families. It supplies them with medical care and psychological support, and it guarantees their protection and right to privacy before, during, and after trial.

Final Thoughts

Many questions relating to victims' rights remain unanswered. However, an international criminal jurisdiction has granted victims the right to participate at any stage of the proceedings. It has been recognized that victims play a unique role in helping to establish the reality of the heinous crimes prosecuted before the International Criminal Court, and thus should be allowed to participate under the best conditions. It also shows the will of the international community to overcome the sole logic of punishment and to establish some sort of restorative justice.

LARCENY/THEFT

The terms *larceny* and *theft* are often used interchangeably, however, *theft* is the more general term and encompasses many different acts of taking property, including larceny. The United States government defines larceny/theft as the unlawful taking and/or possessing of property that belongs to another individual. The majority of statutes require three elements for an act to be considered larceny. The perpetrator must (1) actually take or attempt to take (2) someone else's property, and (3) there must be criminal intent (*mens rea*) to take the property, knowing that it belongs to another. Larceny/theft is one of the four Part I property crimes reported yearly by the the Uniform Crime Reporting (UCR) Program of the Federal Bureau of Investigation (FBI). The FBI distinguishes larceny/theft from motor vehicle theft, as each crime encompasses its own definition within the UCR Program. The other two categories of Part I property crimes are burglary and arson.

Within the UCR Program definition, larceny encompasses many aspects of theft, including shoplifting, pickpocketing, and bicycle theft. Force is not used in cases of larceny-theft. When force is applied when taking property, the crime receives the more severe label of robbery or burglary. Although motor vehicle theft is not considered larceny, the theft of items within the vehicle or on the vehicle (e.g., car parts, stereos) would be considered larceny, as long as force was not applied. Less severe aspects of theft, including embezzlement, writing fraudulent checks, and other forms of forgery are not included within this definition of larceny-theft. Instead they occupy a place within the UCR Program's Part II crime list.

Types

Grand/Petit Larceny

The definitions of grand (big) and petit (little) larceny differ across jurisdictions. Each jurisdiction will set a monetary amount that signifies the point at which a crime's classification changes from petit larceny to grand larceny. Many jurisdictions will use the value of \$1,000 to make this determination. Larceny in which the value of what the perpetrator took or attempted to take is \$1,000 or more is labeled grand larceny. Thus if the value of the merchandise in question is less than \$1,000, the crime is considered petit larceny. The following forms of larceny-theft could be either grand or petit, simply depending on the worth of the goods.

Direct Taking

Shoplifting is the direct taking of merchandise from a retail store without paying for the goods. According to a recent *USA Today* report, occurrences of shoplifting continue to rise as economy struggles. Shoplifting is often one of the first forms of larceny/theft committed by young children. This can include taking penny candy from a grocery store or taking a toy at a garage sale. Other forms of direct taking include bicycle theft, pickpocketing, and taking motor vehicle parts.

Indirect Taking

Indirect taking is defined by the individual's actions immediately after obtaining the merchandise. It is the actions taken by the individual that determine whether the act should be labeled larceny. For example, finding a purse on the subway is not a crime. However, if the individual who finds the purse takes the money and credit cards from the purse, with the intent of using the funds for his or her own purpose, the act becomes larceny. Jurisdictions differ in their responses to indirect-taking crimes. Some choose to follow the common law model, stating that larceny occurs only if the individual intended to commit the crime (*mens rea*) after discovering the property in question. Other jurisdictions use the Model Penal Code, Section 223.5, which defines an act to be larceny if the individual does not attempt to return the merchandise to its rightful owner.

Deceptive Taking

Deceptive taking implies the use of deception to carry out larceny. The perpetrator may pretend to be someone else in order to coerce an individual into turning over his or her property. The perpetrator may also withhold information from the individual to get the property. If an individual willingly turns over or gives his or her property to the perpetrator, but the individual does so based on the deceit or deceptive promises of the perpetrator, larceny has occurred.

Prevalence

Although occurrences of larceny/theft are declining, this crime accounted for the largest percentage of property crimes committed in 2006. Approximately 66.6% of 2006 property crimes were larceny/theft. Furthermore, according to the UCR Program reports, \$5.6 billion worth of property was taken in instances of larceny/theft. The UCR Program distinguishes between types of larceny, but not between petit and grand larceny. Except for the "other" category, which encompasses 33% of larceny occurrences, the majority of larceny/theft occurrences were found to be from motor vehicles (26.5%). This does not include the taking of motor vehicle parts and/or accessories. Following theft from motor vehicles were shoplifting (13.2%), theft from buildings (12.6%), theft of motor vehicle accessories (9.7%) and bicycles (3.5%), purse snatching (0.6%), theft from coin-operated machines (0.5%), and pickpocketing (0.4%).

Larceny rates were reported to have declined from 2005 by 3.5%. Furthermore, in the past decade, larceny rates have declined 23.7%. The national average of reported larceny/theft was 2,206.8 per 100,000 people. This rate was found to be highest in cities outside a metropolitan area (2,864.6 per 100,000). The reported rate for both metropolitan statistical areas (2,303.1 per 100,000) and nonmetropolitan areas (992.1 per 100,000) was under the national average.

The prevalence of larceny/theft varies across United States geographical regions. The highest rate of larceny/theft occurs in the South (41.3%). The West is second (22.8%), followed by the Midwest (22.5%), and the Northeast (13.4%). Furthermore, the leading property crime in the South, Midwest, and Northeast is larceny/theft.

Larceny/theft is the lowest reported property crime in the West, however, trailing behind motor vehicle theft (36.8%) and burglary (23.1%).

Clearance/Arrest

In 2006, the UCR Program's reports showed that more cases of larceny/theft were cleared, either by arrest or other exceptional circumstances, than those of any other property crime except arson (18%). Larceny/theft cases were cleared 17.4% of the time. Although this is greater than the burglary (12.6%) and motor vehicle theft (12.6%) rates, it remains exceptionally low compared to the clearance rates of all violent crimes. Violent crime clearance rates in 2006 ranged from 25.2% (robbery) to 60.7% (murder). The Northeast has the highest rate of larceny/theft clearances (20.6%), followed by the South (17.6%), the Midwest (17.1%), and the West (15.7%).

In most jurisdictions, whether a crime is judged grand or petit larceny is what defines the crime as either a felony or a misdemeanor. Grand larceny is usually categorized as a felony and punishable with time in prison. Petit larceny is usually categorized as a misdemeanor, punishable by no more than one year in jail. However, punishments may vary, especially if the jurisdiction utilizes structured sentencing guidelines, which take into account not only the severity of the current offense, but the perpetrator's prior criminal history as well.

Supreme Court Cases

The United States Supreme Court, as well as lower courts, has repeatedly examined the issue of larceny/theft. A 1971 California case examined the idea of indirect taking in *People v Stay* (96 Cal. Rptr 651 [Cal. App. 1971]), in which the defendant was found guilty of grand larceny for collecting shopping carts and demanding that the store give him a "reward" for the return of the carts. The Court held that the carts were not lost and a reward was not justified.

The 2001 case of *People v Rohlfson* (Illinois Court of Appeals 752 N.E.2d 499) examined the concept of deceitful taking. A prisoner called an elderly woman from the prison phone, claiming to be her relative and asking her to send \$1,500 to the jail for him. Correctional officers intercepted

the check before it could be cashed, and the court found that the funds had been obtained through deception and charged the individual with larceny.

The United States Supreme Court debated the issue of ownership of property in a 1952 case, *Morrisette v. United States* (342 U.S. 246). The defendant claimed that he took scrap metal, believing it to be abandoned property. Abandoned property, or property without an owner, cannot be the victim of larceny/theft. The court held that ownership in this case could not be proven, and the defendant was cleared.

LAUTENBERG AMENDMENT

The Lautenberg Amendment is a protective measure for victims of domestic violence. The U.S. Congress enacted it to protect abuse victims, as the possession of a firearm by a chronically abusive partner greatly increases the chance that the victim will receive a fatal injury. In 1996, Congress passed the Omnibus Consolidated Appropriations Act of 1997, enacting the Domestic Violence Offender Gun Act in the process. Because the bill

was sponsored by Senator Frank Lautenberg (D) of New Jersey, the Domestic Violence Offender Gun Act became known as the Lautenberg Amendment. The Lautenberg Amendment made possessing, receiving, or shipping a firearm a federal crime for individuals who had been convicted on a misdemeanor domestic violence charge or had been convicted of child abuse. In addition, the Lautenberg Amendment made it illegal to sell or issue a firearm or ammunition to such an individual. It is considered an amendment to the Omnibus Crime Bill and Safe Streets Act of 1968, also known as the Gun Control Act (GCA) of 1968, as it did not provide exceptions that the GCA had included for law enforcement and military personnel, and it expanded the GCA list of persons who were prohibited to possess, receive, or ship firearms. The lack of exceptions for law enforcement and military personnel is the root cause for the extent of the controversy surrounding the Lautenberg Amendment.

Twentieth-Century Gun Control Legislation

During the 20th century, numerous gun control measures were enacted. The National Firearms Act of 1934 called for the registration and taxation of a specific classification of weapons (e.g., machine guns, sawed-off shotguns, silencers). In 1938, the Federal Firearms Act set certain policies for the sale of firearms and introduced the federal firearms license for businesses that sold or repaired firearms. The aforementioned GCA of 1968 provided an extensive set of regulations. The most notable of these regulations dealt with age requirements for purchasing a firearm; the prohibition of certain individuals from possessing firearms, namely felons; the prohibition of shipping firearms and ammunition through the mail system; and specific sentencing guidelines for offenders who used firearms during a crime. When the Brady Handgun Violence Prevention Act was passed in 1994, it was viewed as the next major gun control legislation. The Brady bill instituted the requirements for states to conduct background checks on handgun sales and a 5-day waiting period for the background check. The Violent Crime Control and Law Enforcement Act of 1994 outlawed the manufacturing of numerous types of assault rifles and high-capacity magazines that held more than 10 rounds of ammunition.

The Lautenberg Amendment strengthened the then recently passed Violence Against Women Act (VAWA) of 1994. The VAWA made it against the law for an individual under a restraining order to possess a firearm; however, like its predecessors, it provided exceptions for law enforcement and military personnel. Under the Lautenberg Amendment, individuals under a restraining order for domestic violence are prohibited from possessing a firearm, including those who would normally have the authority to do so under the auspices of law enforcement or military duties.

Arguments Against and For the Lautenberg Amendment

Anti-Lautenberg Amendment

A contingent of law enforcement and military officials opposed the Lautenberg Amendment on the grounds of constitutionality in the following areas: (1) its application to misdemeanor domestic violence and not to other misdemeanor crimes; (2) its lack of application to individuals who are convicted of felony-type domestic violence charges; (3) its unfair singling out of law enforcement. This anti-Lautenberg Amendment contingent complained that the amendment would cause job losses for both law enforcement and military personnel. Another concern for this group is the retroactive nature of the Lautenberg Amendment. The amendment applies to individuals convicted after the date of enactment as well as to individuals with domestic violence convictions dated before the law went into effect.

Pro-Lautenberg Amendment

Advocates of the Lautenberg Amendment, including certain law enforcement organizations, argue that upon receiving a conviction for domestic violence or child abuse, individuals who had been trusted with the duty and corresponding authority to protect society should be seen as having abandoned their posts and be identified as convicted abusers. According to the amendment's supporters, law enforcement or police duties do not afford convicted abusers extra rights or protection from the consequences of their convictions. Those in favor of the Lautenberg Amendment also

argue that since so many domestic violence and child abuse incidents are reported to the police every year, the victims reporting the abuse should not have to worry that the officers responding to their calls may be abusers.

LAW ENFORCEMENT ASSISTANCE ADMINISTRATION (LEAA)

The Law Enforcement Assistance Administration (LEAA) was the first program of significant federal aid for state and local law enforcement and criminal justice efforts. Moreover, the Safe Street Act and LEAA began a new era of federal assistance to state and local governments that continues to this day. Thus the LEAA program, which was initiated in response to the social turbulence of the 1960s and continued through the 1970s, educated and trained thousands of criminal justice personnel.

The 1960s was one of the most tumultuous decades in American history. Serious crimes reported to the police nearly tripled. Robberies doubled. Violent crime rates soared. However, the serious crime conviction rate fell during this

period. Crime had reached epidemic proportions, but the criminal justice response to it was seriously flawed. Race relations turned contentious and deadly. Assassinations and random violence increased. In 1962, federal troops were dispatched to the University of Mississippi to enroll the first Black student, James Meredith. The next year federal troops were sent to the University of Alabama. Medgar Evers, an NAACP field secretary, was assassinated by a Ku Klux Klan member in June 1963. Then, in September, four young black girls were murdered in a racially motivated bombing of the Sixteenth Street Baptist Church in Birmingham, Alabama, by Klan members. Two months later, on November 22, 1963, President John F. Kennedy was assassinated in Texas. The 1965 Watts race riot in Los Angeles left 34 dead. Malcolm X, a Black political activist, was assassinated in New York in 1965. In 1966, a sniper at the University of Texas at Austin shot 45 people, killing 14. There were massive race riots in 1967. The first, in Newark, New Jersey, lasted 26 days and left 26 dead. Then in Detroit, Michigan, a riot went on for 8 days and resulted in 43 deaths.

Civil rights leader Martin Luther King Jr. was assassinated on April 4, 1968, in Memphis, Tennessee. Then on June 6, presidential candidate Senator Robert Kennedy was assassinated in Los Angeles. Later that year, the police handling of the protests and resulting riot at the 1968 Democratic National Convention marked the event as a “police riot.” In 1969, Charles Manson and his followers killed actress Sharon Tate and three others in Los Angeles. In the waning days of that year, political activist and deputy chairman of the Illinois chapter of the Black Panther Party Fred Hampton was killed under suspicious circumstances by a police tactical unit. Opposition to the war in Vietnam resulted in massive political protests throughout the country, including the killing of four Kent State students at an antiwar demonstration in 1970.

When violence and social protests increased during the 1960s, leading to criminal acts, the need for a federal response became apparent. President Lyndon Johnson prodded Congress into creating the President’s Commission on Law Enforcement and Administration of Justice and the passage of the 1965 Law Enforcement Assistance Act. The act created the Office of Law Enforcement Assistance

in the Department of Justice to fund demonstration projects to improve the methods of criminal justice administration at state and local levels. This program existed until 1968, when its functions were transferred to the Law Enforcement Assistance Administration.

The 1967 President's Commission's report, *The Challenge of Crime in a Free Society*, recommended that the federal government provide financial assistance to state and local governments for law enforcement purposes, broadly defined as all components of the criminal justice system. Congress responded in 1968 by passing the Omnibus Crime Control and Safe Streets Act. Title I of the act established the Law Enforcement Assistance Administration. The goals of LEAA were (1) to reduce crime and delinquency by encouraging and assisting states in developing comprehensive plans to fight crime, (2) to make block grants to states to provide funding to carry out these plans, (3) to conduct research in law enforcement, and (4) to provide leadership and guidance to state and local governments in their efforts to improve the criminal justice system. The planning assistance, grants, guidance, and leadership were made through state and regional planning agencies. The planning agencies developed comprehensive state plans to improve law enforcement and developed state and local programs and projects. It was a massive centralized federal effort for the decentralized planning, funding, and execution of criminal justice projects at the local level.

The act also established the National Institute of Law Enforcement and Criminal Justice as LEAA's research arm to make grants to public agencies, colleges and universities, and private organizations to conduct studies and research in criminal justice issues. After 1974 the institute also served as a national clearinghouse for the exchange of criminal justice information. In 1979, the functions of the institute were absorbed by the National Institute of Justice.

The program was not without criticism. Congress intended that all criminal justice components would receive grants; however, the law enforcement theme led many to believe it was a "police program." This misunderstanding caused funding problems, with the majority of monies allocated to law enforcement agencies. Block grants to the states were criticized for lax control

over the money. There were instances of wasteful use of funds. The program suffered from unrealistic expectations. It was assumed that money was the answer to reducing the crime problem and winning the "war on crime." However, after the expenditure of \$7.5 billion, critics pointed out that the program had no real impact on crime. There was one downturn in crime statistics in 1972; however, the reported violent crime rate continued to rise throughout the 1970s. The composition of the planning agencies reduced the transparency of state and local efforts and complicated police-community relations. The planning agencies were composed of only law enforcement agencies and local units of government, which minimized input from community and citizen groups, particularly minorities. The red tape involved was a nightmare for many grant recipients.

Many current criminal justice professors began their education with LEAA grants and loans. And many programs, or variants of these programs, begun with federal seed money are still in place. Thus LEAA demonstrated that the federal government can play a valuable role in helping state and local governments deal with the crime problem. The research emphasis of LEAA is ongoing. Criminal justice planning, analysis, and evaluation became important concepts as a result of LEAA.

LIFESTYLE THEORY

In 1978, Michael Hindelang, Michael Gottfredson, and James Garofalo published *Victims of Personal Crime: An Empirical Foundation for a Theory of Personal Victimization*. In this book, the authors stated that people play a role in their own victimization by engaging in lifestyles and making certain lifestyle choices that make them more accessible to offenders and easier targets for crime. This assertion started a new line of inquiry in criminological theory by suggesting that the choices victims make either increase or decrease their chances for criminal victimization.

Heretofore, scholars had suggested that crime victims could be held at least partially responsible for their victimization due to characteristics they possessed. In the early years of victimology, these characteristics often were presented as typologies. For example, Benjamin Mendelsohn identified five types of victims: innocent victims, victims with minor guilt, victims as guilty as offenders, victims who were guiltier than offenders, and most guilty victims. Similarly, Hans Von Hentig expanded the idea of the victim typology by naming 12 types of crime victims: young, female, elderly, mentally defective, immigrants, minorities, dull normals, depressed, acquisitive, lonesome and heartbroken, tormentors, and blocked, exempted, and fighting. Finally, Thorsten Sellin and Marvin Wolfgang developed a more generalizable list of victim types: primary victims, secondary victims, tertiary victims, and mutual victims. These typologies were helpful in the early stages of victimological research in that scholars could note and understand that criminal victimization was not an entirely random event, and that crime victims could be identified based on some personality or demographic characteristics they held. One problem with these typologies, though, was that many of the victim types represented individuals who had very low rates of victimization (e.g., youth, females, and elderly people). In addition, these typologies tended to suppose that victims were to blame for their own victimization. The emergence of the lifestyle theory of victimization allowed scholars to move beyond the victim-blaming issues and present a better understanding of the relationships between victims and offenders in the context of lifestyles and locations.

Lifestyle Constraints

The main assertion of lifestyle theory is that various lifestyles of individuals place them in greater proximity to criminal offenders, thus they themselves increase their odds of criminal victimization. Also, individuals with certain lifestyles may make better choices for offenders because of their value as individuals, their valuable possessions, or their unwillingness to protect themselves or their property adequately. Michael Hindelang and his colleagues define lifestyle as daily activities and leisure activities in which individuals participate on a routine basis. The concept of lifestyle includes choices individuals make freely and within imposed constraints, as well as behaviors influenced by societal structures and expectations.

To elaborate, lifestyle includes behavioral expectations of persons occupying various social roles. For example, we do not expect new parents to go out partying and drinking all the time after the birth of their child. We anticipate that they will stay at home and take care of their infant. At the same time, young single men and women are “allowed” more freedom to engage in alcohol-related leisure activities. They are unlikely to have important responsibilities at home and can, therefore, go out and have fun. Another example involves the behavioral expectations associated with employment. Those who are employed are usually expected to go to work in the morning, and then leave work in the early evening. They cannot travel across town to see movies whenever they want. It is only after their working hours that they can choose activities like joining a community theater group, playing on a soccer team, or going to happy hour with friends. These lifestyle impositions are attached to individuals who are parents or employees, for example, simply *because of* the social expectations we hold for the persons occupying these roles. Because much crime is committed on the street, parents staying home would be less likely to come into contact with criminally motivated others than the hypothetical young, single, partying men and women.

Another antecedent of lifestyle includes constraints on behavior by virtue of economic status, education, and familial obligations. An example of this type of limitation may be economic circumstances. An individual who wants to go out to

dinner is restricted to restaurants that fall within his or her price range. This individual may not have personal transportation and thus may be restricted to restaurants that are within walking distance of his or her home or can be reached by public transportation. However, the individual who is wealthy and does not have personal transportation may eat at any restaurant he or she wants and can take a cab there. If someone is restricted to eating at restaurants that are close to his or her home, then the amount of crime in that neighborhood and in the area of the restaurant influences the safety of that individual.

A final type of influence over individuals' lifestyles is the individual and subcultural adaptations to behavioral and structural constraints. Here an example could be an individual who, because of a worsening economy, has been laid off and has been unable to find another job. This individual could adapt to this increasingly difficult and depressing situation by drinking and becoming addicted to methamphetamines. Another individual in the same circumstances might take up ultimate fighting and use a punching bag to let out frustrations. Still a third individual might sink down into a deep depression and never get out of bed. Those belonging to various subcultures are likely to handle challenges and opportunities in ways that are similar to other members of the same subculture. To specify, members of highly religious affiliations may turn to prayer in order to get divine guidance on how to get through a difficult economic, jobless time, whereas members of outlaw biker gangs may turn to illegal activity to maintain an income in a tough economy. In these examples, obviously, the persons are more or less likely than each other to encounter criminals and criminal behavior, and, as such, more or less likely to become victims.

Michael Maxfield summarizes these differing lifestyle constraints (or lack thereof) and choices by pointing out that they ensure that criminal victimization is not a random event but a highly patterned and potentially somewhat predictable event. He hammers home his point by noting that middle-aged married women in professional occupations have widely differing and significantly lower risks for criminal victimization than unemployed single males in their early 20s.

Contexts Related to Victimization Risk

Some researchers have noted that lifestyle choices and restrictions shape personal victimization risks in the context of location. Thus there are high-risk locations and low-risk locations for criminal victimization, and the risks associated with these locations may vary, increase, or decrease depending on the type of crime examined. For example, a college student going to the library to study seems to be making a safe lifestyle choice when criminal victimization is considered. And, the library may, indeed, be quite safe when considering the risks for assault or murder. However, the campus library may be relatively risky when other crimes, such as theft, are considered. A library patron who is studying, takes a break to use the restroom, and leaves books and a backpack unattended is at a high risk for larceny. The library stacks may also be dangerous places for victimization by lewd exhibitionists. But, one is quite unlikely to be murdered in a library, particularly by a crazed heroin addict who is looking for money for another fix.

Time, according to Garafalo, is another context in which lifestyle and criminal victimization may intersect. According to this perspective, time of day may be highly significant when examining people's risks for criminal victimization. In this way, the social milieu of any particular location changes depending on the time of day and the regular activities that go on in that location at various times of the day. For example, in a large city, there may be a location where prostitutes solicit during the evening hours. This location may be near shops and restaurants. During the day, the shops are open, the restaurants are serving lunch to businesspeople, and there are no prostitutes. However, at night, the shops close, the restaurants are serving alcoholic drinks, and the prostitutes are soliciting drunken patrons as they leave the establishments. Individuals who frequent that location during the day are presumably relatively safe. But, patrons who hang around that location at night are relatively unsafe, particularly if their normal thinking and functioning is impaired by alcohol.

Additional Considerations

In a further exposition of lifestyle theory, Marcus Felson suggests that while criminal offenders do not need much skill, and criminal opportunities

are frequent and everywhere, criminals do try to minimize their risks for getting interrupted, injured, or caught. Some of the elements most offenders will consider are when homes are vacant, the amount of money individuals may be carrying with them, and the times the public transportation system is busy or relatively vacant. Other considerations may include the probability that any particular potential victim may fight back and try to thwart the ensuing robbery. Whether or not the liquor store owner has a gun under the counter and can readily grab it are lifestyle factors that would-be offenders may consider. In this way, individuals' lifestyles influence their chances for criminal victimization when their choices affect offenders' perceptions of their vulnerability or predictability.

Similarly, individuals may or may not consider the safety issues in particular locations and, as such, may or may not take necessary defensive measures. They may be unaware of their personal surroundings or may choose to ignore the factors that make certain locations dangerous. As Richard Sparks has noted, individuals may facilitate predation by routinely failing to take certain precautions. Thus exposure to offenders is not just a lifestyle but involves a certain amount of choice, which is influenced by individuals' perceptions of the likelihood of victimization. People choose to recognize or ignore the threat of crime when structuring their daily activities.

Much of the research on lifestyle theory of criminal victimization includes examinations of demographic characteristics. While demographics are not elements of lifestyle, *per se*, they are part of the lifestyle model because they tend to be indicators of the structural constraints and role expectations that shape individuals' lifestyle behaviors, activities, and choices. For example, research tends to find that married people do not go out at night for leisure activities as often as single, separated, or divorced people. Here, then, being married can serve as a proxy measure of exposure to offenders. Also relevant is the notion that most offenders victimize people who are like themselves. As such, young, poor, Black males are the most likely perpetrators of crime and they are also the most likely victims of such aggression.

Some scholars of lifestyle theory have delved into examinations of cities and neighborhoods. These scholars have noted that the lifestyles of the

residents in these locations tend to be similar to each other, and the "typical" lifestyle of the neighborhood (or a small town) can influence the amount of crime and victimization that occurs in that location. Here, then, the concept of lifestyle is expanded into a more macro notion. An example of this is a neighborhood where most residents know each other. In a location such as this, stealing would be hard to conceal. Personal items belonging to individuals are known to belong to these individuals, and if someone else took possession of an item, others in the neighborhood would know to whom that item belonged. So, the lifestyle of this type of community is one that involves frequent interaction with neighbors, and the fact that most residents of this type of community engage in that type of lifestyle solidifies the relative safety residents experience. Another example of a location with which specific lifestyles are associated is New York City. Many residents of New York City do not own cars because cars are expensive, there is not enough parking for them and the parking that is available is expensive, and the streets are constantly clogged with traffic. Further, the public transportation system is easy to use, cheap, and sufficient for the needs of most residents. As such, many residents of New York City take the subway or buses to get where they need to go. While this lifestyle is more dangerous than driving a car, most New Yorkers make this choice. Thus the residents of New York City have higher risks for criminal victimization than residents of the aforementioned smaller community, but that increased danger is just one of the characteristics associated with the lifestyle of the larger city.

Time, in the context of history, is also a relevant element in the examination of lifestyle and its relationship to criminal victimization. To elaborate, in the early years of settlement in the United States, walking around was the mode of transportation that most people adopted. Cars and other vehicles had not been invented, and horses were not available to all. Towns were sparsely populated, and residents were spread out across the prairie and farming lands. Walking from home to town was not practical and only happened infrequently when farmers traveled to the county seat to get supplies (or made some such similar trip). With the increase of horse ownership, the trip from home to town or home to home was speedier, thus, the amount of

stealing increased, as well as the stealing of horses. With the advent of cars and further increases in the number of horses and buggies, crime became much more of a problem, as getting away from the scene of the crime was easier and faster. In addition, cars, horses, and buggies were increasingly targets of theft. At the same time, with the advent of improved transportation came the industrial revolution, and cities continued to grow, people owned more and more of value, and populations were denser. At this point in history, crime increased due to the increased opportunities and the ability to hide in the crowd as well as the speed of escape. As is clear from this type of historical examination, lifestyle is an element of the historical process of city growth and industrialization.

Role in Understanding Victimization

Lifestyle theory provided an alternative path toward understanding criminal victimization. Previously, victims may have been blamed for the devastating events in their lives, and scholars' understanding of victims was limited to simple characteristics they possessed. The additional consideration of individual lifestyle has allowed scholars to understand that victimization is not a random event, but one that can be assessed and potentially predicted. Risks for victimization can be evaluated by considering the locational exposure of individuals to offenders and any precautions (or lack thereof) such individuals may take because of their perceptions of the safety of the locations they frequent. This theory gave rise to another theory of criminal victimization, routine activities theory, and to analyses of personal safety and effective safety precautions.

LIGHTING

Improved street lighting serves many purposes, one of them being the prevention of crime in public places. Street lighting improvements are not always implemented with the expressed aim of preventing crime; pedestrian and traffic safety may sometimes be viewed as more important aims. But while the notion of lighting streets to deter lurking criminals may seem too simplistic, it is relevant to the prevention of crime in urban centers, residential areas, and other places frequented by potential criminals and potential victims.

Explanations of the way that street lighting improvements could prevent crime can be grouped into two main perspectives: (1) a situational crime prevention measure that focuses on reducing opportunity and increasing perceived risk through modification of the physical environment, and (2) a method of strengthening informal social control and community cohesion through more effective street use and investment in neighborhood conditions. The first perspective predicts decreases in crime especially during the hours of darkness, while the second perspective predicts decreases in crime during both daytime and nighttime.

Background

Contemporary interest in the effect of improved street lighting on crime began in the United States during the dramatic rise in crime in the 1960s. Richard Wright and his colleagues note that many towns and cities embarked upon major street lighting programs as a means of reducing crime, and initial results were encouraging. This proliferation

of projects led to a detailed review of the effects of street lighting on crime by James Tien and his colleagues, funded by the National Evaluation Program of Law Enforcement Assistance Agency funding. Their report described how the 103 street lighting projects originally identified were eventually reduced to a final sample of only 15 that were considered by the review team to contain sufficiently rigorous evaluative information. With regard to the impact of street lighting on crime, Tien and his colleagues found that the results were mixed and generally inconclusive. However, each project was considered to be seriously flawed because of such problems as weak project designs, misuse or complete absence of sound analytic techniques, inadequate measures of street lighting, poor measures of crime (all were based on police records), and insufficient appreciation of the impact of lighting on different types of crime.

In the United Kingdom, very little research was carried out on street lighting and crime until the late 1980s. Kate Painter notes that there was a resurgence of interest between 1988 and 1990, when three small-scale street lighting projects were implemented and evaluated in different areas of London. In each location crime, disorder, and fear of crime declined and pedestrian street use increased dramatically after the lighting improvements. In a recent narrative review, Ken Pease notes that “the capacity of street lighting to influence crime has now been satisfactorily settled.” He also recommended that the debate should be moved from the sterile “Does it work or doesn’t it?” to the more productive “How can I flexibly and imaginatively incorporate lighting in crime reduction strategy and tactics?” (p. 72).

Evidence of Effectiveness

The best source for evidence of the effectiveness of lighting in preventing crime comes from systematic reviews carried out by Brandon C. Welsh and David P. Farrington. Systematic reviews use rigorous methods for locating, appraising, and synthesizing evidence from prior evaluation studies, and they are reported with the same level of detail that characterizes high-quality reports of original research. They include explicit objectives, explicit criteria for including or excluding studies, extensive searches for eligible evaluation studies from all

over the world, careful extraction and coding of key features of studies, and a structured and detailed report of the methods and conclusions of the review.

Studies were included in Welsh and Farrington’s systematic review if they met a number of criteria, including if improved lighting was the main intervention, if there was an outcome measure of crime, and if the evaluation design was of high methodological quality. A number of search strategies were employed to locate studies meeting the criteria for inclusion, including searches of electronic bibliographic databases, searches of literature reviews on the effectiveness of improved lighting on crime, and contacts with leading researchers. Thirteen studies met the inclusion criteria, eight from America and five from Britain.

From the 13 evaluations, it was concluded that improved street lighting had a significant desirable effect on crime, with a weighted mean odds ratio of 1.27. This means that crimes decreased by 21% in experimental areas compared with control areas.

Table 1 summarizes the results of all 13 studies. This shows the odds ratio for total crime in each study, plus its 95% confidence interval and statistical significance. It can be seen that only three studies (in Portland, New Orleans, and Indianapolis) had odds ratios less than 1, meaning that improved street lighting was followed by an increase in crime, and in no case was this increase significant. The other 10 studies had odds ratios greater than 1, meaning that improved street lighting was followed by a decrease in crime, and in 6 cases this decrease was significant (or nearly so, in the case of Atlanta). Therefore, the hypothesis that more lighting causes more crime can be firmly rejected.

American Studies

For the most part, residential neighborhoods were the setting for the eight American street lighting evaluations. Improved street lighting was considered to have a desirable effect on crime in four evaluations: those in Atlanta, Milwaukee, Fort Worth, and Kansas City. In all four cases, the odds ratio was 1.24 or greater, which corresponds to a 19% decrease in crimes or better. Improved street lighting was most clearly effective in reducing crimes in the Fort Worth evaluation. Crimes decreased by 22% in the experimental area and

Note: N = only night crimes measured; ND = night and day crimes measured.

increased by 9% in the control area. In the other four evaluations, the improved street lighting was considered to have a null effect on crime (evidence of no effect). For example, in Portland, there was little evidence that improved street lighting had led to any reduction in nighttime crime. The results of the meta-analysis of all eight American studies yielded an odds ratio of 1.08, which was not significant. Overall, crime decreased by 7% in experimental areas compared with control areas.

The key dimension on which the eight effect sizes differed seemed to be whether they were based on data for both night and day (as in the Atlanta, Milwaukee, Fort Worth, and Indianapolis studies) or for night only (as in the other four studies). For the four night–day studies, the average effect size was a significant odds ratio of 1.28, meaning that crime decreased by 22% in experimental areas

compared with control areas. For the four night-only studies, the odds ratio was 1.01, indicating no effect on crime. Therefore, the eight American studies could be divided into two blocks of four, one block showing that crime reduced after improved street lighting and the other block showing that it did not. Surprisingly, evidence of a reduction in crime was only obtained when both daytime and nighttime crimes were measured, although this feature may be a proxy for some other aspect of the different evaluation studies.

Unfortunately, all the American evaluations (except that of Indianapolis) are now rather dated, since they were all carried out in the 1970s. More recent American evaluations of the effect of improved street lighting need to be conducted. British evaluations, which were all published in the 1990s, are discussed next.

British Studies

The five British street lighting studies were carried out in a variety of settings, including a parking garage and a market, as well as residential neighborhoods. All studies measured crime at night and during the day. Improved street lighting was considered to be effective in reducing crime in four studies (those in Bristol, Birmingham, Dudley, and Stoke-on-Trent). In the fifth study (done in Dover), the improved lighting was confounded with other improvements, including fencing to restrict access to the parking garage and the construction of an office near the main entrance.

In the Dudley study, crime was measured using before and after victim surveys in experimental and control areas. Large samples were interviewed—431 in the experimental area and 448 in the control area. The response rate was 77% in both areas before and 84% after (of those interviewed before). Substantial crime reduction benefits were achieved after one year of the improved street lighting scheme. In the experimental area, the prevalence of all crime decreased by one quarter (24%), while only a marginal decrease (3%) in the prevalence of all crime occurred in the control area. Also, the incidence (average number of victimizations per 100 households) of all crime decreased in both the experimental and control areas—41% and 15%, respectively. The decrease in the experimental area was found to be significantly greater than the decrease in the control area.

The Stoke study also used large victim surveys, with an 84% response rate before and an 89% response rate after (of those interviewed before). The incidence of crime decreased by 43% in the experimental area, by 45% in the adjacent area, and by only 2% in the control area. When differences in the pretest victimization rates (prevalence and incidence) in the areas were controlled, it was found that the changes in experimental and adjacent areas were significantly greater than in the control area. There was also evidence of diffusion of crime prevention benefits to an adjacent area that did not receive the lighting improvements.

When the odds ratios from the five studies were combined, crimes decreased by 38% in experimental areas compared with control areas (OR = 1.62). These more recent British studies agree in showing that improved lighting reduces crime. They did not

find that nighttime crimes decreased more than daytime crimes, suggesting that a “community pride” theory may be more applicable than a “deterrence/surveillance” theory.

Conclusion

It can be concluded that improved street lighting should be included as one element of a situational crime reduction program. It is an inclusive intervention benefiting an entire neighborhood, and it leads to an increase in public perception of safety. Improved street lighting is associated with greater use of public space and neighborhood streets by law-abiding citizens. Especially if well targeted to a high-crime area, improved street lighting can be a feasible, inexpensive, and effective method of reducing crime.

M

MALE VICTIMS OF PARTNER VIOLENCE

Male victims of partner violence, which is a major health hazard in the United States, is defined as domestic abuse that is perpetrated by women against men or by men against men. Many people either have never heard of it or do not believe that it is possible for men to be abused. Generally, society defines intimate partner abuse (also known as domestic violence/domestic abuse/intimate partner violence) as women and children being abused—not men. Although males are not abused as frequently as female victims of domestic violence, it happens more frequently than most people realize. Approximately 35% of victims of intimate partner violence are male. However, women who are assaulted are nine times more likely than men to report it to the police and five times more likely to tell a friend or relative.

It is estimated that in the United States a woman is severely assaulted by her male partner every 15 seconds and that a man is severely assaulted by his female partner every 14.6 seconds. About 8%–10% of male-to-female partner violence is reported, whereas only 1% to 2% of female-to-male partner violence is reported. A woman is nearly twice as likely to use an object when she assaults a male partner, which can increase the level of potential injury. According to the Centers for Disease Control and Prevention (CDC), the National Center for Injury Prevention and Control (NCIPC),

and the U.S. Department of Justice, each year women experience about 4.8 million intimate-partner-related physical assaults and rapes and men are the victims of about 2.9 million intimate-partner-related physical assaults. Intimate partner violence resulted in 1,544 deaths in 2004. Of these deaths, 25% were males and 75% were females.

More importantly, before any victim can be helped, one must be willing to believe in the possibility of abuse. Not all abused persons present with black eyes, bloody nose, swollen lips, missing teeth, or a willingness to talk about it. On the contrary, for many abused persons, intimate partner violence is difficult and embarrassing to discuss.

Types of Abuse

Physically abused victims are pushed, kicked, slapped, stabbed, cut, spat on, tripped, knocked down, shot, bitten, raped, stalked, and so on. Economically abused victims are not allowed to have money or to secure jobs. The abuser may give them an allowance, but the victim may have to show receipts for every penny spent. If the victim works, the abuser may control his or her paycheck. The abuser may buy everything the victim needs or may not buy any of the basic requirements of life in order for the victim to sustain life (food, clothing, medical care or assistance, etc.). In psychological abuse, victims are subjected to mental games to keep them confused and/or to make them feel inadequate or even mentally ill (i.e., victims may see or hear something, but the abuser will tell the victim the incident did not happen, when in

fact it has happened). After a while, victims may doubt themselves and believe everything they are told by the abuser. Many victims believe their abusers to be omnipotent and omnipresent. Often, intense counseling sessions are needed to assist victims in accepting their abusers as being simply men and women. For the sake of their emotional well-being, it is imperative for victims and survivors to regain their ego.

One of the abuser's most powerful weapons is isolation. Abusers discourage and threaten victims to keep them from associating with anyone without their consent and outside of their control. This includes the victim's family and friends. The cycle of violence comes in three stages. The tension-building stage is when the victim cannot do anything right to please the abuser. The abuser is extremely critical of everything the victim does and creates a lot of tension within his or her surroundings. The victim does everything to calm the abuser, but it is all to no avail. The second stage is the explosive stage when the victim is attacked. Refusing to take ownership of his or her actions, the batter attempts to justify the behavior by telling victims that the abuse is the victim's fault. If the victim had not done this or had not done that, they would not have "had" to hit them. The third stage is the honeymoon stage when the abuser may or may not ask for forgiveness and is very amorous saying he or she will never hurt the victim again. Victims are often nervous, afraid, and in pain but willing to give the abuser another chance. The honeymoon cycle will only last for a little while and then the cycles of abuse begin. It is estimated that the victim will leave his or her abuser between eight and ten times before he or she leaves for good—this is when the victim becomes a survivor.

Sexual abuse can also occur among male victims. According to local police authorities, females are not the only ones being forced into the sex trade. Many young men and boys, especially runaway teens and preteens, may be forced to perform several acts, including prostitution, drug dealing, stealing, and so on, under the threat of bodily harm or harm to their pets, family members, or other loved ones and friends—abusers are very capable of destroying their victims. Those who comply with the wishes of the abuser are readily abused to keep them under control, and many of those who do not are killed.

Characteristics of Abusers

A batter may feel remorse at first, but this can change quickly. Batterers are in control, and they choose the victim, time, place, violent tactics, and the severity of the assault. The batterer presumes to be entitled to control his or her partner and can become more and more violent with each subsequent event. The primary goal of abusers is absolute power and absolute control over their victims by any means necessary, including maiming and murdering. Even today, domestic violence is one of the best-kept personal secrets. It is a nondiscriminatory, albeit not always discrete, personal relationship hazard. It is multifaceted. It crosses all social, economic, and racial boundaries. Many victims will not talk about the abuse in their lives because of embarrassment, and they attempt to keep it a secret. Abusers can be pillars of the community and a great friend to neighbors and co-workers alike, but behind closed doors or in their own home, they can be very violent. One of the most underreported serious public health problems in the United States is still male intimate partner abuse. As stated, only 1% to 2% of female-to-male partner violence is reported.

Abusers are not mentally deranged people who cannot control themselves. One of the most infamous abuses of women was Henry Tudor, better known as King Henry VIII. He forced women to marry him and threw them away when he tired of them (e.g., he had six wives and murdered one of them by using a false charge of treason). Domestic violence is a learned behavior. It is learned through observation, experience, culture, and family. Boys who observe family violence are more likely to be violent toward their family when they become adults if they have remained in the family violence setting until they reach age 6 years or older—girls who observe family violence are more likely to accept violence toward themselves and the family when they become women if they have remained in the family violence setting until they reach age 10 years or older. A mentally ill person may be abusive, but the underlying cause of the mental illness is not the reason for the intimate partner violence. Each behavior must be addressed separately.

In relationships between males and females and males with males, the abuse techniques are basically the same. The primary goal is absolute power

and absolute control over the victim. In society, the male is perceived as the dominant force and he is usually in command of his surroundings. He is powerful, fearless, strong, invincible, and protective of the weaker people around him, but when he is afraid, he cannot show his fear. Just as women are afraid and/or embarrassed to let people know about the abuse they are experiencing, male victims of abuse present with these same fears and apprehensions as their female counterparts, with one major exception. Many people do not believe men when they identify—men may be laughed at for being afraid or showing fear. Men, girlfriends, and wives alike are the perpetrators of male partner abuse. The abusers are professionals and non-professionals, and absolutely no one is immune to abuse. Male partner abuse is not anything new, but it must be investigated and given credibility to protect the victims. Often men are not afraid of their abusers, but they simply tire of fending off the abuser and leave them in order not to hurt them.

Support for Victims

To provide support and safety for all people, it must be acknowledged that there is domestic violence/intimate partner abuse in various relationships, including in dating and marriage relationships and in the lesbian, gay, bisexual, transgender (LGBT) community.

Not all men who are abused are single men—some of these men are married to abusive women. Women publicly embarrass or humiliate their husbands; withhold affection; threaten to harm themselves, their children, or others; control family finances; and blame men for their behavior. Although the laws available for abused women and children are also available to men, the resources are not in place.

Homosexual men are, and can be, abused by their partner. The Chicago Domestic Violence Help Line reports the aforementioned victims complain about the lack of services (not always feeling comfortable and safe or feeling isolated and “different”), and discrimination is still a problem. Some court personnel and service providers in the domestic violence community still hold negative attitudes toward LGBT clients. Fifty-seven percent of the LGBT community complained about difficulties accessing community-based services and

50% of straight men complained about difficulties accessing community-based services. The Chicago Domestic Violence Help Line, the Mayor’s Office on Domestic Violence, and the Center for Urban Research and Learning state that 55 service providers have reported that straight males also complain about the lack of specific services, being taken seriously, and having to “jump through extra hoops” to prove themselves to be victims of abuse.

Regardless of one’s race, religion, or lifestyle preference, the Chicago Domestic Violence Help Line is available to help 24 hours a day, 7 days a week, by calling 1-877-863-6338, TTY 1-877-863-6339. The Help Line has access to a language bank for people who do not speak English. Those who are abused are not alone—they must be helped to realize, and accept, that they are not the “only” person in the world being abused. Many domestic violence service providers, volunteers, and survivors are waiting to help them. However, these service providers cannot find abused persons without help. Those abused must make the first step and reach out for help and support. Whether victims choose to leave or to stay with their abuser, service providers must support their autonomy. Counseling and safety planning must be made readily available, and their final decision, whatever it is, must be respected.

MANDATORY REPORTING STATUTES

Problems with measuring the extent of child abuse and elder abuse, as well as with addressing the needs of such victims, begin with the need to identify the abusive activity. Unfortunately, statistics on both child and elder abuse are questionable for a variety of reasons. First, the actions involved are most often done out of the eyesight of the public and are easily hidden from agents who can intervene. Second, there has been a historic reluctance to intervene in activity that many view as a family matter. Third, many individuals who potentially see or know about such abuse do not know who to contact and how to proceed with making a claim of abuse. For these and other reasons, the figures on both child and elder abuse are open to question. One major effort to address the problems of reporting and measuring child and elder abuse is the enactment of mandatory reporting statutes that outline who is responsible for making reports, who is to receive the reports, the information that is to be collected, and what is to be done with the information. This entry examines these statutes.

At first glance, it seems reasonable to assume that mandatory reporting is a good first step in dealing with child and elder abuse. Interestingly, however, there has been a great deal of resistance to mandatory reporting and numerous criticisms of these efforts. Most states now have some form of mandatory reporting law for abuse. The Centers for Medicare and Medicaid Services mandates several procedures that facilities receiving federal funds and reimbursement for services must follow, and these regulations require reporting of elder abuse and neglect to state-level agencies.

A couple of important observations can be drawn from existing state statutes. First, mandatory reporting requirements are restricted primarily

to public employees or employees of agencies that would most likely have contact with potential victims. Examples of these individuals are social workers, teachers, physicians, mental health professionals, law enforcement personnel, hospitals, and nursing homes. Second, the specificity of who must report suspected abuse varies somewhat from state to state. Some states require attorneys, the clergy, banks, financial advisors, and others who could become aware of abuse to file reports. In Florida, bank employees and inspectors of public lodging establishments must report. In Ohio, the clergy and attorneys are required to report. Persons not included in these categories have no legal obligation to make a report of suspected abuse.

The advent of mandatory reporting statutes resulted in increased numbers of child and elder abuse cases coming to the attention of the authorities. Data on the extent of child abuse and elder abuse reveal generally increasing levels over time. This is at least partly a result of mandatory reporting statutes as well as of changes in the social perception that such abuse is unacceptable and that society has a right to intervene in what some consider a family matter.

The greatest criticism of mandatory reporting efforts has been that they do little more than encourage reporting. Often, these reporting laws fail to define abuse, fail to identify to whom abuse is to be reported, fail to impose penalties for failure to report abuse, and fail to outline what to do with the reports once they are made. Although many states have taken steps to address these gaps in the statutes (such as passing legislation outlining penalties for nondisclosure), many problems still exist in many jurisdictions.

Several other problems also have been identified with mandatory reporting statutes. First, the laws typically deal only with the reporting of abuse and fail to provide resources to follow up on the reports or to do something about the problem. Second, critics claim that these laws intrude into the privacy of the individual. This is particularly problematic in terms of elder abuse where the victim is a legal adult and may be making a choice not to contact the authorities about his or her victimization. Another example of the privacy concern involves laws requiring physicians to report suspected cases of abuse, which critics contend violates client-physician confidentiality. Third,

mandatory reporting in relation to elder abuse is perceived by critics as reinforcing ageism by focusing on the victim rather than on the offender. These laws identify the victim of abuse and often prompt reactions that may include removing the victim from the home or blaming the victim for the abuse, rather than focusing on the perpetrator. Similarly, these efforts place the elderly into a category with children, the mentally ill, and others who are incapable of making decisions for themselves. Critics contend that these laws, therefore, fail to treat the elderly as adults and, consequently, degrade the elderly victim.

Despite mandatory reporting laws, many reports are never made or are made after a lengthy delay. When events are not reported in a timely enough fashion, it is not uncommon for the receiving agency to determine that the event was unfounded. This may not be because there was no abuse. Rather it may be because abuse cannot be proven because of the delay in reporting. A prime example involves a General Accounting Office review of the Centers for Medicare and Medicaid Services, the oversight agency for nursing homes. Although the Centers mandate various reporting guidelines for abuse and neglect allegations, most state agencies are not promptly notified in accordance with regulations. Indeed, almost two thirds of the reports are made 2 or more days after the required deadline. This delay is problematic because it makes it difficult, if not impossible, for the investigating agencies to undertake a meaningful investigation. After a delay, it is often difficult to talk to witnesses, the witnesses or victims cannot recall the event clearly, or the evidence is no longer available for the police or other investigators.

Mandatory reporting statutes have been a major change in society's response to elder and child abuse. Despite any shortcomings of the legislation, the goal of identifying and addressing these forms of victimization is important. With the continued growing interest in elder and child abuse, these statutes will probably become stronger and more effective.

MASS MURDER AND SUICIDES IN CULTS

Although mass murders and mass suicides in new religious movements (popularly known as cults) have attracted media publicity, their occurrence is rare in proportion to the overall numbers of present-day religious organizations—at least 2,000 in the United States alone. This entry discusses some religious movements in which mass murders and/or suicides occurred and then assesses the commonalities among them.

Religious Movements

The Peoples Temple

The Peoples Temple was the first to attract publicity in recent times. Founded by James Warren Jones in California in 1955, it became affiliated with the mainstream Disciples of Christ. Jones was particularly concerned to promote interracial harmony. He also claimed miraculous powers, although most of his “miracles” were faked. Believing in an imminent nuclear holocaust, and facing mounting criticism, Jones and about 1,000 followers moved to Guyana in 1974, where they transformed 300 acres of tropical jungle into a self-sufficient community.

When his critics persisted, Jones came to regard suicide as the alternative to failure. He organized “white nights”—regular rehearsals for mass suicide, which took place at night. Congressman Leo Ryan visited Jonestown to investigate and was

shot dead by one of the Jones followers. Jones then ordered the mass suicide, instructing his aides to shoot anyone who tried to escape. In all, 919 people died.

Branch Davidian Waco

David Koresh (born Vernon Wayne Howell) gained control of the Branch Davidian Waco group, an Adventist group, in 1988, and most of the members lived in the compound near Waco, Texas, where he expounded the Bible for long periods, with particular reference to the Book of Revelation.

Koresh claimed exclusive rights to all the group's women and, allegedly, had sexual relationships with minors. He had expertise in firearms and was believed to have modified semiautomatic handguns into fully automatic ones. After four federal agents were killed in an unsuccessful attempt to serve a search warrant, Attorney-General Janet Reno authorized a Federal Bureau of Investigation (FBI) assault on February 28, 1993. The siege lasted until April 19 when fire broke out. It is not known whether the fire was started by the FBI or by Koresh's followers. Seventy-four members were killed in the fire, and five died in the February confrontation.

The Solar Temple

The Ordre du Temple Solaire (OTS—Order of the Solar Temple) was a Templarist group, whose multiple deaths occurred in 1994, 1995, and 1997, in several different locations, the first of which were roughly simultaneous. The deaths seem to have formed part of a ceremony. On October 4, 1994, four adults and a child were found, having been stabbed and burned to death, at Morin Heights, Canada, in the home of OTS co-leader Joseph di Mambro. On October 5, just after midnight, 23 burnt bodies were discovered in Cheiry, Switzerland; the members had been shot and were arranged in a circle. At 03:00, another 25 bodies were discovered at Les Granges sur Salvan, Switzerland. An additional 16 Solar Temple members were found dead in similar circumstances, near Grenoble in France in 1995, and in 1997, five more members were found burned to death at St-Casimir, Quebec.

The organization's interests were eclectic, encompassing Egyptian death rituals, Rosicrucianism,

alternative medicine (co-leader Luc Jouret was a medical doctor), reincarnation, and belief in supernatural "Ascended Masters." The group may have regarded fire as the means of transition to the star Sirius, which featured largely in its thinking.

Aum Shinrikyo

In 1985, Aum Shinrikyo, founded by Shoko Asahara, gained notoriety when five followers released sarin gas into trains in the Tokyo subway on March 20, killing 12 people and injuring hundreds more. This incident was one of several violent acts perpetrated by the group. On May 5, 1995, a device was found at another subway station, designed to release hydrogen cyanide, with the potential to claim 20,000 victims. Asahara was arrested and subsequently sentenced to death.

A blend of Buddhism, Indian yogic practices, Japanese folk religion, and apocalyptic ideas derived from the Book of Revelation and Nostradamus, Asahara's teachings predicted an imminent apocalypse. Asahara's goal was to commission 30,000 *shukkesha*—renunciates who would survive Armageddon—and turn Japan into a paradise. The murders may have been *poa* (salvational murders), aimed at assassinating unbelievers, releasing them from evil *karma*.

Heaven's Gate

Some 39 members of Heaven's Gate were found poisoned in a large house on the outskirts of San Diego, California, in March 1997, apparently as a result of orchestrated suicides. Each member lay on a bunk bed, covered with a purple shroud, and wearing black trousers and Nike trainers. Each had packed a suitcase, as if embarking on a journey. Marshall Herff Applewhite, the leader, taught that extraterrestrials had come to collect them in a spacecraft, docked behind the Hale-Bopp comet, and which could be boarded by undergoing death.

The Movement for the Restoration of the Ten Commandments of God

In 2000, more than 500 members of the Movement for the Restoration of the Ten Commandments of God were found, having been burnt alive in a remote part of Uganda. The doors and windows of the church were barricaded from

the outside, preventing the congregation from escaping. Subsequent investigation revealed large numbers of bodies (possibly more than 1,000) buried in mass graves. The group was an African Independent Church, whose members claimed visions of the Virgin Mary and prescribed an austere lifestyle, aiming to heighten the standards of the Ten Commandments, in anticipation of an imminent apocalypse.

The reasons for the deaths are still unknown. The movement is largely undocumented, the local populace speaks little English, and little forensic evidence was collected. Members may have believed that immolation secured entry to heaven; alternatively, leaders may have wished to prevent dissatisfied members from reclaiming forfeited possessions.

Assessment

These organizations are diverse, with different religious antecedents. They are not predominantly “religions of the dispossessed,” often attracting well-educated, professional people. They were not principally youth movements; the average age of the Heaven’s Gate member was 47 years old. Common to all were apocalyptic expectations, in most cases associated with the turn of the millennium. All groups perceived advantages afforded by death, and their calamitous endings may relate to their worldviews, rather than to authoritarian leadership or “brainwashing.”

MEDIA COVERAGE OF VICTIMS

The focus of this entry is on media coverage of crime victims. Although there is not much research specifically on this topic, there is considerable published work on the media’s general coverage of crime. This research highlights the types of crime presented in the media, the processes used to construct these stories, and whether the nature of the coverage affects public perceptions or criminal justice decision making. It is within this body of research that one can begin to understand the key issues related to media coverage of crime victims. Two issues are discussed here. First, the role of the media in highlighting concerns about the treatment of crime victims is discussed. Second, concerns about the quality and the effects of coverage on crime victims are highlighted.

Concerns About Treatment of Victims

There is little doubt that the status of victims in the criminal justice system has changed dramatically during the last 30 years. Policy initiatives, special units, and financial resources have been created or designated to help improve the plight of victims generally. The victims’ rights movement strived to address many complaints voiced by crime victims, including that they were being retraumatized by a criminal justice system that was cold, uncaring, and unwilling to recognize the significant harm caused by crime. The media, both news and popular outlets, have played an important role in raising awareness and in creating opportunities for policy makers and advocates to address various grievances voiced

by crime victims. For example, the victims' rights movement generally, as well as efforts to help special classes of victims such as child, domestic violence, and hate crime victims, has benefited from media coverage that has highlighted issues related to improving the treatment of these victims.

The media have contributed to significant social change to help victims in multiple ways. The decisions media personnel make about covering certain issues and ignoring other issues can influence agenda priorities. Moreover, how an issue is covered helps to define the contours of the debate about an issue. The unfortunate reality is that there is a limited amount of bureaucratic, financial, and political resources available to address social problems. Priorities need to be set, and often it is the direct or indirect media coverage that determines what issues are given serious consideration. For example, the victimization of child, rape, and domestic violence victims was not considered an important policy issue until the 1970s. Although several factors contributed to recognizing the need to help these victims, media coverage helped to legitimize their concerns.

One way that the media have consistently brought national attention to concerns about victims is by publicizing the facts and circumstances of a specific high-profile case. Such cases then provide a window of opportunity to manufacture new legislative initiatives and strategies to improve the treatment of victims. Consider the creation and widespread adoption of Megan's Law. Megan Kanka was 7 years old when she was raped and murdered by a convicted sex offender. Her parents were outraged when they learned the perpetrator lived across the street, and they thought that they had a right to know that a convicted sex offender lived nearby. National media coverage of this case contributed to the development and adoption of statutes that required convicted sex offenders, when released from prison, to register with the police who then in certain circumstances notify neighbors. The federal government and nearly 20 states have adopted some version of Megan's Law since the case received publicity. The media's role in institutionalizing Megan's Law is only one example of how specific victim cases create opportunities for policy discussions and political change. Other cases include how media publicity of the Francine Hughes case, who

was brutally beaten by her husband for many years before killing him, contributed to policy initiatives to assist domestic violence victims; how the abduction and murder of Adam Walsh increased concerns about missing and exploited children; and how the murder of Matthew Shepard helped create bias-related crime legislation.

Not only did the media help to determine policy agendas by bringing attention to previously ignored harms to crime victims, it also specifically influenced the contours of policy debates about these topics. In his book *Sense and Nonsense About Crime*, Sam Walker discussed that although many policies introduced to support victims' rights would have no effect on crime and might harm the criminal justice system and victims, adopting many of the laws to assist victims were symbolically important. The important point here is that the media emphasized specific legislative initiatives and ignored others. Indeed, the initiatives that were emphasized were those that were much more likely to be consistent with a conservative, crime-control approach. Stuart Scheingold, Toska Olson, and Jana Pershing demonstrated this in their study examining the passage of Washington State's Community Protection Act. This legislation focused on addressing many issues, but the issue that was perhaps the most controversial and generated national media attention was its sexual predator provisions. Specifically, the legislation allowed authorities to bring convicted sex offenders who were being released from the criminal justice system into the civil system to be committed until they are no longer dangerous to the public. Although victim advocates and supporters of the legislation presented both punitive and preventive approaches to respond to sex offenders, it was the punitive measures that resonated in public debates and that were emphasized within the legislation that was passed.

Quality and Effects

Media coverage of specific policy issues have caused policy makers, media executives, and reporters to consider how they could better respond to the needs of crime victims. Numerous symposiums, conferences, and articles have been written that describe the harm caused by reporters when covering victims callously and unsympathetically.

The publication of body bags, bloody scenes, and graphic accounts of a crime may help boost ratings for media organizations but at the same time do considerable harm to crime victims and family members. The public forums that have been conducted on this topic have led to positive reforms in newsrooms and to improved coverage that better balances the public's right to know with an individual's right to privacy. Consider, for example, the Pulitzer Prize-winning story by a *Des Moines Register* reporter about the traumas caused by rape. Although it is media policy to not name a rape victim because of the risk of stigmatization, the victim agreed to be identified for this particular story and the story was a sensitive, gripping account that led to better public understanding about rape trauma. Importantly, the story and the identification of the victim resulted in a healthy debate within newsrooms and by victim advocates about the sensitive coverage of rape and naming rape and other victims in news stories.

During this same period of time, as policy advocates were able to harness media attention to open policy windows that produced significant social change, the media have been criticized for their coverage of crime victims on multiple fronts. The media have been criticized for misrepresenting the presentation of victimization in the news. Specifically, the media distorts the images of victimization presented to the public by emphasizing certain types of victims and ignoring others. Research indicates an inverse relationship between official and constructed realities of crime. For example, crimes that are least likely to occur, such as murder, are most likely to be presented in the news. Similarly, individuals at the greatest risk of becoming a crime victim are often the least likely to be presented in the news. One of the critical variables that influences the salience and prominence of a crime incident in the news is the race of the victim. Murders of African American and other minority victims are significantly less likely to be covered by the media and, if covered, receive much less space compared with crimes with murdered White victims. Specifically, crimes involving White victims may be as much as five times more likely to be covered compared with crimes involving minority victims. Moreover, not only are minorities deemphasized as victims, they tend to be overemphasized as defendants in the news.

Several other victim characteristics either increase or decrease the likelihood that a particular story is covered prominently in the news. First, age is an important variable. Although children and elderly victims are much less likely to be victimized compared with young adults and adults, their victimizations draw considerable media attention. These victims are deemed worthy of protection because of their innocence. Children and elderly victims are ideal victims and are emphasized in the news because it is assumed that they did not contribute to their victimization in any way. Second, the gender of the victim is also an important variable. Female victims are newsworthy, especially when victimized by violent crimes. A third characteristic reflects the status of a victim. Status may be identified in different ways, such as in the occupation of the victim, the community where the victim lives, or in past involvement in the criminal justice system. Crimes with victims from suburban and wealthy communities are much more likely to be covered in the media, and those involving victims with criminal histories are less likely to be covered.

Crime news is produced through a bureaucratic process where reporters develop routines that lead to the efficient production of news about crime. Crime stories are important news stories, and thus, a news organization must devote considerable resources to provide the public with multiple crime stories every day. On average, a newspaper may present ten crime stories. Among the key solutions that increase the efficiency of news production is the media's reliance on easily accessible and cooperative news sources. Specifically, research indicates that most of the sources cited in crime news stories are affiliated with a criminal justice agency. Police officers, especially departmental public information officers, are the most important source used by reporters because most media organizations emphasize the beginning stages of the criminal justice process. Reporters rarely contact crime victims for their perspective about a crime incident, and thus, their views are excluded from crime news coverage. If a story is a potentially important news story, however, reporters will make an effort to contact the victim to discuss the crime. If a victim cooperates, and is able to provide an emotional response to their questions, the story increases in importance.

Role in Understanding Victimization

This entry has highlighted two viewpoints about media coverage of crime victims. On the one hand, the media has, at times, been a champion for the cause of victims, has helped bring attention to previously ignored issues, and has influenced policy makers to consider implementing changes that will better assist victims. On the other hand, there are numerous concerns with the nature of media coverage as some victims are covered extensively, but many victims are ignored. The result is a limited understanding of victimization in society and policies are passed that help some but not all victims.

MEDICAL AND MENTAL HEALTH SERVICES

Victims of sexual assault and other bodily crimes have extensive post-assault medical needs, including

injury detection and care, medical forensic examination, screening and treatment for sexually transmitted infections (STIs), as well as pregnancy testing and emergency contraception. Because of the traumatic nature of sexual assaults, victims may also develop mental health issues. This entry discusses the services available to victims for their post-assault medical and mental health needs.

Medical Services

Although most victims are not physically injured to the point of needing emergency care, traditionally, police, sexual assault crisis centers, and social service agencies have advised victims to seek treatment in hospital emergency departments for a medical forensic examination. The body of a victim is a crime scene, and because of the invasive nature of sexual assault, a medical professional, rather than a crime scene technician, is needed to collect the evidence. The “sexual assault exam” or “sexual assault kit” usually involves plucking head and pubic hairs; collecting loose hairs by combing the head and pubis; swabbing the vagina, rectum, and/or mouth to collect semen, blood, or saliva; and obtaining fingernail scrapings in the event the victim scratched the assailant. Blood samples may also be collected for DNA, toxicology, and ethanol testing.

Victims often experience long waits in hospital emergency departments because sexual assault is rarely an emergent health threat, and during this wait, victims are not allowed to eat, drink, or urinate so as not to destroy physical evidence of the assault. When victims are finally examined, they may get a cursory explanation of what will occur and it often comes as a shock that they have to have a pelvic examination immediately after such an egregious, invasive violation of their bodies. Many victims describe the medical care they receive as cold, impersonal, and detached. Furthermore, the examinations and evidence collection procedures are often performed incorrectly. Most hospital emergency department personnel lack training in sexual assault forensic examinations, and those trained usually do not perform examinations frequently enough to maintain proficiency.

Forensic evidence collection is often the focus of hospital emergency department care, but sexual assault victims have other medical needs, such as information on the risk of STIs/HIV and prophylaxis

(preventive medications to treat any STIs that may have been contracted through the assault). The Centers for Disease Control and Prevention and American Medical Association (AMA) recommend that all sexual assault victims receive STI prophylaxis and HIV prophylaxis on a case-by-case basis after risk assessment. However, Annette Amey and David Bishai point out that analyses of hospital records have shown that only 34% of sexual assault patients are treated for STIs. Yet, data from victims suggest much higher rates of STI prophylaxis: 57% to 69% of sexual assault patients reported that they received antibiotics during their hospital emergency department care. But not all victims are equally likely to receive STI-related medical services. Victims of nonstranger sexual assault are significantly less likely to receive information on STIs/HIV or STI prophylaxis, even though knowing the assailant does not mitigate one's risk. In addition, Rebecca Campbell and associates found that Caucasian women were significantly more likely to get information on HIV than ethnic minority women.

Post-assault pregnancy services are also inconsistently provided to sexual assault victims. Only 40% to 49% of victims receive information about the risk of pregnancy. The AMA and the American College of Obstetricians and Gynecologists recommend emergency contraception for victims at risk for pregnancy, but only 21% to 43% of sexual assault victims who need emergency contraception actually receive it. To date, no studies have found systematic differences in the provision of emergency contraception as a function of victim or assault characteristics, but hospitals affiliated with the Catholic Church are significantly less likely to provide emergency contraception.

In the process of the forensic examination, STI services, and pregnancy-related care, doctors and nurses ask victims many of the same kinds of questions as do legal personnel regarding their prior sexual history, sexual response during the assault, what they were wearing, and what they did to "cause" the assault. Medical professionals may view these questions as necessary and appropriate, but sexual assault victims often find them upsetting. As a result of their contact with emergency department doctors and nurses, most sexual assault victims have stated that they felt bad about themselves (81%), depressed (88%), violated (94%),

distrustful of others (74%), and reluctant to seek further help (80%). Only 5% of victims in S. E. Ullman's study rated physicians as a helpful source of support, and negative responses from formal systems, including medical, significantly exacerbate the posttraumatic stress disorder (PTSD) symptomatology of the victims. Victims who do not receive basic medical services rate their experiences with the medical system as more hurtful, which has been associated with higher PTSD levels.

Mental Health Services

The mental health effects of sexual assault are devastating; many victims experience this trauma as a fundamental betrayal of their sense of self, identity, judgment, and safety. Dean Kilpatrick and associates note that between 31% and 65% of sexual assault victims develop PTSD and 38% to 43% meet diagnostic criteria for major depression. These sequelae are largely from the trauma of the sexual assault itself, but as noted, negative responses from the legal and medical systems exacerbate victims' distress. Clearly, victims may *need* mental health services, but there has been comparatively less research on what services they actually receive and whether that care improved their psychological health. Victims may obtain mental health services in myriad ways (e.g., treatment outcome research, community clinics/private practice, and specialty agencies such as sexual assault crisis centers), and their experiences vary considerably as a function of treatment setting.

First, some victims receive mental health services by participating as research subjects in randomized control trial treatment outcome studies. This option is available only to sexual assault victims who live in communities where such research is being conducted, and who fit eligibility criteria. However, this kind of research is not intended to provide large-scale services; the goal is to establish empirically supported treatments that can then be disseminated for wider scale benefit. Indeed, the results of these trials suggest that cognitive-behavioral therapies, such as cognitive processing therapy and prolonged exposure, are effective in alleviating PTSD symptoms. The victims who participate in these trials receive high-quality treatment and benefit tremendously, but this is not the experience

of the typical sexual assault victim seeking post-assault mental health services.

A second, and more typical, way victims receive post-assault mental health services is community-based care provided by psychologists, psychiatrists, or social workers in private or public clinic settings. More victims receive mental health services in these settings relative to treatment outcome studies, but these are still highly underused with serious accessibility limitations. Most victims who seek traditional mental health services, for example, are Caucasian. Ethnic minority women are more likely to turn to informal sources of support (e.g., friends and family) and may not necessarily place the same value on formal psychotherapy. Victims without health insurance are also significantly less likely to obtain mental health services.

When victims do receive community-based mental health services, it is unclear whether practitioners are consistently using empirically supported treatments. Two state-wide random sample studies of practitioners suggest it is unlikely. Most practitioners report using cognitive-behavioral methods with victims of violence (including, but not limited to, sexual assault victims), but almost all practitioners stated they rarely use a single approach and intentionally combine multiple therapeutic orientations and treatments. As a result, it cannot be concluded that most victims receive empirically supported care in traditional, community-based mental health services. As is often the case in the efficacy-effectiveness-dissemination research cycle, it can take quite a while for evidence-based practice to become standard care.

Few studies have examined if and how victims benefit from community-based mental health services. In general, victims tend to rate their experiences with mental health professionals positively and characterize their help as useful and supportive. Whether positive satisfaction results in demonstrable mental health benefits is largely unknown, although Campbell and associates found that community-based mental health services were particularly helpful for victims who had had negative experiences with the legal and/or medical systems. Some mental health practitioners have expressed concern about whether their own profession works effectively with sexual assault victims: 58% of practitioners in a state-wide study felt that mental health providers engage in practices that would be

harmful to victims and questioned the degree to which victims benefit from services.

A third setting in which victims may obtain mental health services is specialized violence against women agencies, such as sexual assault crisis centers and domestic violence shelter programs. Sexual assault crisis centers help victims negotiate their contact with the legal and medical systems, and they also provide individual and group counseling. These agencies are perhaps the most visible and accessible source for mental health services for sexual assault victims as they provide counseling free of charge and do not require health insurance. As with traditional mental health services, there is still evidence of racial differences in service utilization as Caucasian women are significantly more likely to use sexual assault crisis center services than ethnic minority women.

Little is known about the therapeutic orientations and treatment approaches used in sexual assault crisis centers, but current data indicate a strong feminist and/or empowerment theoretical orientation (e.g., shared goal setting, focus on gender inequalities, and identification of sexual assault not only as a personal problem but as a social problem too). With respect to counseling outcomes, April Howard and associates compared self-reported PTSD symptoms precounseling and postcounseling among victims receiving sexual assault crisis center counseling services, and they found significant reductions in distress levels and self-blame over time and increases in social support, self efficacy, and sense of control. Because the studies did not examine the content of services or include comparison groups, it is unclear whether these observed improvements are attributable to the services provided.

MEDICAL EXAMINER RESPONSE TEAM (MERT)

A Medical Examiner Response Team (MERT) is a group of medical and law enforcement professionals charged with investigating certain fatalities. The goals of a MERT include identifying remains and determining the cause and manner of death. This entry discusses the medical examiner/coroner system in the United States, the death investigation performed by MERTs, the controversies involved with death investigations, and the future of forensic pathology.

Medical Examiner/Coroner System

The medical examiner/coroner system originated in the English crowner system of the 900s. The “crowner” was a public official who collected duties for the king on deaths, hunting, and other events. In 1860, in the United States, Maryland began requiring a physician be present at coroner proceedings. This was the start of a shift in the United States toward the medical examiner system where physicians certified deaths rather than sheriffs and other public officials. In the United States today, fewer than 10 states retain coroner systems with the remaining having medical examiners. A contemporary medical examiner is a physician but not necessarily a specialist in pathology.

The medical examiner/coroner office (ME/C) is responsible for issuing death certificates recording the identity of the deceased, the time of death, the cause of death, and the manner of death. The *cause of death* can be a disease, injury (e.g., firearm), or poison, and there can be primary and contributing causes of death. The mechanism of death is not always listed but is the physiological cause of death such as hemorrhage from a firearm injury. The *manner of death* has limited options: natural, accidental, homicide, suicide, unclassified, or undetermined. A classification of homicide means only one person killed another and does not

mean a crime occurred (e.g., self-defense). The determination of murder is made by a court of law.

Local and state law classifies deaths that must be reported to the ME/C. Generally the following deaths are reportable: violent, sudden, or unexpected deaths; fatal injuries; poisonings; fires; and deaths in police custody, after a medical procedure, or involving transportation.

There are multiple goals of the medical examiner investigation. A primary goal is to identify remains to permit family notification. Other goals are determination of cause and manner of death, interval from injury to death, injury documentation, and recovery of evidence. ME findings support prosecution of perpetrators of homicides.

Death Investigation

After a death is reported, the medical examiner begins a death investigation. The procedures after a reported death vary according to the number of deaths at the scene and other circumstances. The investigation might include an on-scene investigation or an autopsy. A death certificate is signed, and in complex cases, a report may be prepared. If there is a legal proceeding, the medical examiner often testifies as an expert witness.

Autopsy

An autopsy performed by an ME/C is a medicolegal autopsy. It is similar to an autopsy performed in a hospital in that it includes both an external and internal examination of the body as well as a microscopic examination of the organs and testing of body and body fluids such as blood, urine, bile, and vitreous (eye fluid). A medicolegal autopsy differs from a hospital autopsy in that a pathologist can collect and interpret physical evidence relating to the manner of death (e.g., metal shavings). As part of an autopsy, a forensic pathologist reviews the deceased's personal history, medical records, toxicology, and laboratory information.

Scene Investigation

A scene investigation is usually completed in suspected homicides and suicides. The size and specialties of a MERT vary depending on the number of reported fatalities, the size and nature of the event, and the condition of the remains.

Scene investigators at a firearm homicide might include a medical examiner, autopsy technician, and forensic photographer/crime scene photographer. Crime scene technicians and/or death investigators collect evidence. These persons might be either law enforcement personnel or medical examiner personnel. Medical examiner and death scene investigators typically handle remains, whereas police investigators handle other physical evidence such as personal possessions.

In contrast, a mass fatality event such as a plane crash or a school shooting would require a larger mass fatality MERT or even aid from the federal Disaster Mortuary System (DMORT system).

Typical members of a mass fatality response team include the following:

- Forensic pathologist
- Forensic odontologist (dentist)
- Police crime scene investigator/death scene investigator—investigate scene; collect and preserve evidence while maintaining chain of custody
- Forensic photographer
- Fingerprint examiner and technician
- DNA analyst
- Radiologist or technician (X-ray)
- Laboratory scientist/toxicologist/microbiologist/trace evidence technician
- Autopsy technicians/morgue staff
- Forensic anthropologist—examines biological characteristics of the deceased and bones; determines age at death, sex, race, and stature; as well as aids ME in determining circumstances surrounding death. Identify antemortem pathology or abnormalities such as healed fractures or disease and perimortem trauma.

Controversies

The primary goal of a MERT is identification of remains. Medical examiners have a professional guideline to identify remains using scientific standards such as dental records or DNA, which can take days. This can be frustrating for families or public officials who might want quicker identification of remains using nonscientific methods such as visual identification or circumstantial information (pocket contents or seating charts). Unlike a hospital autopsy, permission of next of kin is not

required for a medicolegal autopsy. In many jurisdictions, a judge can order an autopsy despite a family's objection.

Future

The availability of DNA technology has brought new questions to the field. Although some states have DNA databases of convicted felons, there is nothing comparable with existing fingerprint databases and there is debate about the legality and constitutionality of a DNA database. In addition, a national backlog of forensic DNA evidence remains.

An emerging international trend is to use the results of forensic pathology in advancing public health. For example, multiple state medical examiner systems are now members of the Violent Crime Reporting System for the Centers for Disease Control and Prevention and report aggregate data on child deaths.

MEGAN'S LAW

Washington State was the first to pass a law in 1990 authorizing the authorities to notify the public when sex offenders are released into the community. In 1994, the federal government passed the Jacob Wetterling Act, which required all states to develop a registry of sex offenders who had targeted children. The 1996 Megan's Law amendment to this act forced all states not only to register sex offenders but also to notify the community of their presence. Megan's Law was named after 7-year-old Megan Kanka, a New Jersey girl who was raped and murdered by a twice-convicted sex offender who was residing in her neighborhood. Megan's parents argued that had they known their neighbor was a dangerous sex offender who targeted children, they would have taken steps to protect their daughter. Community notification, for better or worse, seems to be with us for the foreseeable future.

It has long been believed that sex offenders, more than other types of criminals, pose a high risk for repetition. In addition, sex offenders often target women and children (who are less able to defend themselves), and their crimes are considered to be particularly offensive. Consequently, the State—which has a duty to protect its citizens—has chosen community notification as one way to discharge this obligation. The government has evidently concluded that the privacy rights of convicted sex offenders are less important than public safety.

The type and method of notification varies widely between and within states, so that not all sex offenders are handled similarly. Distinctions are made between the dangerousness of the offender and the method of notification. For example, New Jersey—which to some extent serves as a model for the rest of the country—uses a three-tier system

that differentiates offender risk and guides the method of notification. Here, convicted sex offenders' level of risk is assessed using the Registrant Risk Assessment Scale, developed by a task force of mental health and criminal justice professionals under the auspices of the New Jersey Attorney General's Office.

The New Jersey model uses a graded system of notification, with those offenders found to be at the highest risk receiving the broadest form of community notification. Here, the county prosecutor's office performs door-to-door notification—within a geographic radius of home and work addresses—of all individuals with whom the offender is likely to come into contact. Sex offenders found to pose low risk must only register with the police at least once per year, depending on the jurisdiction. And, for those offenders in the middle third (moderate risk), the local prosecutor's office notifies administrators at facilities dealing with women or children (depending on the offender's historical victims) within a given geographic area. Recently, identifying information for moderate- and high-risk offenders has been placed on the State Police Web site, thus to some extent eliminating the relative benefit (to the offender) of being found moderate as opposed to high risk.

New Jersey's risk assessment scale is an empirically guided instrument that includes both historical, unchangeable risk factors (referred to as static factors) and current, changeable risk factors (referred to as dynamic factors). New Jersey's scale is more heavily weighted toward static risk factors, with the majority of the points derived from items related to offense history; other risk assessment scales focus more on dynamic factors, such as the offender's current and recent adjustment. In assessing a sex offender's risk, both factors need to be included.

Since the introduction of Megan's Law, many concerns have been identified. For example, it is unknown if the notification programs actually work. Some have even suggested that Megan's Law is a "feel good" remedy that may not prevent future crime. In fact, there has been no empirical validation that establishes the preventive value of the programs. There have also been several cases of vigilantism where citizens have taken it upon themselves to use all sorts of (illegal) tactics to get offenders to move; and in several instances, the wrong person was targeted. In addition, the cost of

the program and the negative impact on real estate values have been cited as unanticipated consequences of the law, whereas the implications of notification through the Internet have yet to be studied. Moreover, several constitutional issues (e.g., rights of privacy and treating different groups of criminals differently) have been raised, with several cases currently before the U.S. Supreme Court.

Controversy has also developed regarding the handling of several subtypes of sex offenders, specifically juveniles, incest offenders, and cases where the sexual encounter was consensual. Because juveniles are a protected class, releasing their identities to communities seems to undermine the foundation of the juvenile justice system (which generally keeps names of minors sealed). And if the names and addresses of incest offenders are made public, the identities of the victims (who, in many cases, have the same last name and address) also become known. Here, the victims lose their confidentiality, which results in revictimization. In addition to adolescent and incest offenders, some "statutory rape" cases—where a minor has had consensual sex with an adult—have also raised concerns. For instance, should an 18-year-old high-school senior, who had consensual sex with his 14-year-old freshman girlfriend, be subjected to community notification? But despite the many problems associated with several aspects of Megan's Law, the public has been overwhelmingly in favor of this type of program. One can only hope that applied social science researchers begin to determine whether the various community notification laws have the desired effect of lowering recidivism, since at present, the value of these laws has little or no scientific support.

MENTAL ILLNESS AND VICTIMIZATION

The victimization of persons with mental illness has both historical significance and contemporary relevance. Because of the nature of mental illness, persons with psychiatric disorders are vulnerable to unfair treatment, including discrimination, stigma, and neglect. This entry situates the complex forms of victimization specific to this population in broader historical perspectives, then critically explores the scope of contemporary forms of mistreatment, and finally turns to the social policies and institutional reforms put in place to protect and to better serve the needs of mentally ill persons.

Historical Perspectives on Victimization

There are three major historical perspectives on the maltreatment of persons with mental illness in American society. First, a major shift in the social management of the mentally ill occurred during the industrial revolution. The shift from family care to institutional care transpired with the decline of rural agricultural communities and the rise of populated urban areas. Many mentally ill people, left adrift without supportive networks, were warehoused in jails and prisons. Championed by Dorothea Dix, the development of mental hospitals was an outgrowth of the modern industrialized society's desire to provide a therapeutic environment for persons in need of psychiatric care. Second, although the number of mental health hospitals grew progressively, they were overcrowded and inadequately staffed. Proponents of patient rehabilitation argued that long-term stays in psychiatric wards had a detrimental effect on the ability of individuals to reintegrate into society. The negative effects of institutionalization were echoed by social labeling theorists who claimed that as a by-product of being labeled "mentally ill," patients suffered depersonalization, a loss of status, and alienation, which exacerbated their symptoms of illness. Patients in mental hospitals were also subjected to various forms of medical experimentation, including electroconvulsive therapy (shock treatment) and psychosurgery (lobotomies). According to many reports, some patients suffered from the results of unsuccessful

surgeries, such as brain damage and other unintended side effects, including, in some cases, death.

A third major development in the mistreatment of the mentally ill occurred as a consequence of the shift from institutionalized care to community-based care, which is referred to as deinstitutionalization. However, despite its positive intentions to improve the lives of persons with mental illness, this public policy failed in many respects. The community mental health movement was underfunded and fragmented. A lack of coordinated care between state hospitals and community agencies meant that former hospital patients were "dumped" into low-income areas without the necessary psychiatric, medical, or social resources to transition successfully back into the community. The systemic failure of deinstitutionalization was particularly harmful for the severely mentally ill. For example, some agencies participate in "creaming" practices whereby they prioritize treatment for people deemed most likely to respond positively to their services rather than those most impaired.

Contemporary Scope of Victimization

Many scholars argue that massive fiscal cutbacks in public mental health services shifted responsibility to law enforcement agencies to manage mentally ill persons. Scholars assert that an apt depiction of this phenomenon is transinstitutionalization. The number of people with mental illnesses in the criminal justice system has increased progressively in recent years; county jails and prisons have become de facto psychiatric institutions at great human cost as well as at public expense. Recent studies report that approximately 16% to 22% of jail and prison inmates suffer from a form of mental illness. Researchers and policy analysts surmise that deinstitutionalization led to the "criminalization of the mentally ill," meaning that individuals with untreated mental illnesses are more prone to police contacts as a result of their disorderly or deviant behaviors. A misguided public perception exists that mentally ill persons are prone to commit violent acts and that police must detain them in the interest of public safety. As a result, those most in need of psychiatric attention, including the homeless, persons with chemical dependency, and those who live in poverty, are more likely to be arrested than to receive care.

Policies, Treatment, and Prevention

Important developments have been aimed at reducing the discriminatory practices against persons with mental disorders. During the community mental health movement, advocacy groups championed the right to treatment by patients as well as their right to refuse treatment. Many states passed legislation to amend the vague and capricious commitment laws. Grassroots organizations, such as the National Alliance for the Mentally Ill, sponsored public education campaigns to increase awareness and fight social stereotypes that portray mentally ill persons as unstable, irrational, and violent. The criminal justice system has also institutionalized reforms to address the needs of mentally ill offenders. Nationwide, jurisdictions are adopting jail alternative programs, including mental health courts, to facilitate in-custody psychiatric assessments and coordinate continued treatment in the community upon release. These trends, however, are not without controversy. Some critical criminologists, for example, argue that these programs widen the net of social control over marginalized populations and raise the specter of coerced treatment.

META-ANALYSIS

Meta-analysis is a systematic literature review technique that uses explicit methods to identify a set of relevant primary studies, followed by objective methods to synthesize results quantitatively from this collection of studies. The approach differs from a traditional narrative literature review, in which findings from multiple studies are discussed and considered qualitatively but are not combined numerically. As an example, a meta-analysis would be a very useful approach to summarize quantitatively evidence on the effects of school-based programs designed to reduce juvenile delinquency, or to synthesize the research on predictors of violent behavior in women. This entry provides a basic overview of the technique of meta-analysis, including its strengths and weaknesses as a form of systematic literature review, as well as provides key steps in the meta-analytic process.

Strengths and Weaknesses

When compared with narrative review, meta-analysis has several advantages. The approach is considerably more objective than a traditional literature review, in part because meta-analysis requires a systematic search for relevant literature and the determination of explicit criteria for study selection into the analysis. A narrative review usually does not implement such criteria and may involve hidden biases because of selecting studies by convenience or through a less systematic search. Furthermore, because a meta-analysis involves explicit, transparent criteria for study identification, selection, and integration, a straightforward

replication of the research is possible. It is much less likely that independent narrative reviews will reach identical conclusions.

Meta-analysis also enables greater precision in estimating the outcome or effect in question. This precision is achieved via the specific techniques used to extract results from studies and to convert these results to common metrics, and the explicit manner by which the individual study results are combined into a single pooled effect estimate. In comparison, a narrative literature review might group study results into general themes or use a more basic quantitative approach such as vote-counting the number of studies that report statistically significant versus nil effects. Vote-counting is a preliminary method of summation, because it does not take into account the magnitude of the effects found across studies or any differences in sample sizes. Because sampling error is a function of sample size, because low-power studies with small samples are less likely to find statistically significant effects than are studies with large samples (given the effects of a similar magnitude). Furthermore, because the meta-analysis algorithm assigns greater weight to larger studies when estimating the pooled effect across studies, the meta-analysis estimate has considerably more statistical power than do the individual studies that compose the estimate.

Another advantage of meta-analysis is its ability to summarize large amounts of information across a set of studies, while also allowing for the examination of potential causes of between-study variation in effect magnitude. Narrative reviews face considerable challenges in effectively summarizing large bodies of literature, in particular with consideration to mediator or moderator effects of research design, treatment style, or treatment effectiveness with different populations.

The most frequent criticism of meta-analysis is that analyses may pool together studies that are incommensurate. In other words, it is meaningless to produce a summary effect for studies that are conceptually (or statistically) dissimilar. Another criticism of meta-analysis is the issue of publication bias. This bias occurs when studies with statistically significant findings are selected for publication more frequently than are studies with nonsignificant findings. The extent to which this is true will serve to bias the results of systematic literature searches, because electronic databases and

other such sources will fail to identify nonpublished, nonsignificant studies.

General Procedure

1. Specifying the Research Question and Form of Research Findings

A meta-analysis begins with the specification of the research question to be assessed. Because the raw data in a meta-analysis consist of the results from independent studies, it is essential that the collection of studies in the meta-analysis examine the same relationship. More specifically, the individual study outcomes should be comparable with respect to conceptual nature, study design, and statistical form.

2. Determining Study Eligibility Criteria

Next, a protocol is developed that contains specific criteria by which studies will be assessed for inclusion in the analysis. Each potential study is examined along these criteria to determine whether the study is eligible for inclusion. For example, a criterion might require the sample to contain at least 100 subjects or the evaluation to include a control group. Studies might be excluded for reasons such as publication in a non-peer-reviewed source or publication outside a particular date range.

3. Systematic Literature Search and Report Retrieval

A systematic search is undertaken, usually with the goal to uncover the entire pool of eligible studies on a given topic. The search often involves key terms searched in multiple bibliographic databases (e.g., PsycInfo and Criminal Justice Abstracts), hand searches of relevant journals, government databases, and bibliographies of studies that meet inclusion criteria, and queries to experts in the field. From the list of studies identified in the literature search, each potentially eligible study is evaluated based on the inclusion criteria to determine whether it will be included in the meta-analysis.

4. Coding and Extracting Data

For inclusion in a meta-analysis, all study findings are transformed into the same format so that

pooling across studies is possible. This format is the “effect size,” which is a standardized index that represents both the magnitude and the direction of the outcome. The derivation of each study’s effect size based on the particular quantitative outcomes presented in the research report allows for a consistent interpretation of findings over the different types of measures and variables.

5. Computing Effect Size Statistics

Several types of effect size measures exist; most of which have more than one method of computation. Commonly used effect size measures include the standardized mean difference (such as Cohen’s *d* or Hedges’s *g*), the odds-ratio, the correlation coefficient, the proportion difference, and the relative risk. The choice of effect size measure used in a meta-analysis depends on both the research question of interest as well as on the data reported in the study.

6. Analysis

The meta-analysis algorithm for determining the pooled mean effect size weights the set of effect sizes by their inverse variance weights, as follows:

$$\overline{ES} = \frac{\sum_i^k (w_i * ES_i)}{\sum_i^k w_i},$$

in which each study’s effect size (*ES*) is multiplied by its inverse variance weight (*w*), summed across all studies *i* through *k*, and divided by the sum of the inverse variance weights for studies *i* through *k*.

The statistical significance of the meta-analysis mean effect size is tested with a Z-test:

$$Z = \frac{\overline{ES}}{SE_{\overline{ES}}},$$

where the standard error is defined by

$$SE_{\overline{ES}} = \sqrt{\frac{1}{\sum_i^k w_i}},$$

and the upper and lower bound 95% confidence intervals are as follows:

$$95\% \text{ C.I.} = \overline{ES} \pm 1.96(SE_{\overline{ES}}).$$

The confidence intervals indicate the precision of the pooled mean effect size; if the confidence interval does not cross zero, then the null hypothesis of no effect is rejected. In other words, the pooled finding across the set of included studies is determined to be statistically significant.

Meta-analysis is a powerful tool for aggregating the findings across a set of studies in a given body of literature, enabling a systematic, objective estimate of a treatment effect across a set of primary studies with potentially conflicting findings.

METHODOLOGICAL ISSUES IN COUNTING VICTIMS

Counting victims of crime has methodological difficulties that can result in an inaccurate portrayal of the number of victims that exist. This is caused by various concerns that originate with the nature of victims as well as with data collection and statistical representations of victims. This entry provides an overview of the general methodological concerns of counting victims as guided by the use of crime/victim counting mechanisms in the United States of the Uniform Crime Reporting (UCR) Program and the National Crime Victimization Survey (NCVS). Finally, some recommendations are provided to enhance the ability of calculating a truer number of crime victims in the United States.

General Methodological Concerns

This entry provides the main reasons why victims are difficult to count. It addresses the concerns with determining the absolute number of victims, type of data collection, gaining access to victims, and statistical concerns of counting victims.

Determining the Absolute Number of Victims

The absolute number of crime victims in the United States has never been captured as the true number of victims is impractical and improbable to determine. It would require researchers to survey each and every individual of the United States, and each individual would have to be completely honest in reporting and recalling his or her victimization. Understandably, such efforts would consume much time and resources, which for the most part are unneeded as it is not as important to know an absolute number as it is to obtain the relative number of victimization instances that occur. Relative numbers or approximations still allow for policies, researchers, and scholars to understand general crime patterns. The concern thus rests on how relative numbers can be gathered to not include too much error or inaccuracies. Two means to obtain relative numbers of victimization are the UCR Program and the NCVS.

Type of Data Collection

One major drawback on the ability to collect information on all crime victimization is that researchers or the government are rarely interested in gathering information on all types of illegal behaviors. For instance, the UCR Program collects information from law enforcement on Part I Index crimes of murder and non-negligent manslaughter, forcible rape, robbery, aggravated assault, burglary, larceny-theft, motor vehicle theft, and arson. Similarly, the NCVS gathers information on crimes of rape, sexual assault, robbery, aggravated assault, simple assault, theft, burglary, and motor vehicle theft. Furthermore, single researchers usually only collect information on the specific crime(s) of interest.

A second concern of crime collection is that jurisdictions define crime differently and that no standardized definitions exist from one locale to another. When crime is defined differently, it adds

to the confusion and inability to use formal records as a measure of victims. Lastly, data collections methods such as the UCR Program are not difficult to use in counting victims as it focuses on counting crime, not victims.

Gaining Access to Victims

As stated, the task of counting and collecting information on all victims is improbable and more than likely impossible. Thus, no source exists that contains a proper sampling frame or list of all victims. For this reason, samples must be used to determine the relative number of crime victims. When samples are correctly gathered, data can be used to infer or generalize findings to the population providing a relative number of crime victims. The main concern of gaining access to victims is how access can be accomplished to gain the proper amount and type of crime victims without being too limiting or exclusionary. To illustrate this concern, the UCR Program uses formal records of law enforcement and only reports crimes known to police officers. If a victim fails to report an offense, he or she would not be counted as a possible victim and would not be included in the sampling frame.

The NCVS is a more accurate resource than the UCR Program to tabulate the relative number of crime victims since it directly pertains to victims. One concern is that it does not sample individuals and instead samples households. Thus, those who do not live in typical residences (e.g., inmates and the institutionalized) or are homeless will not be in the sample. Additionally, the NCVS completes most of its data collection using telephones, a method that excludes those who do not own telephones. Thus, it is difficult to count victims as it is hard to gain access and appropriate samples that fully represent the population of the United States.

Statistical Concerns of Counting Victims

When there is an inability to gather information on a whole population, such as crime victims, samples are used to build statistical models that allow for inferences to be drawn to the population. The process of inference simply allows for the findings of the sample to be generalized to the population. For instance, if 7% of the sample were victims of auto thefts it could be concluded that roughly

7% of the population were victims of auto theft. Yet, for this conclusion to be accurate, numerous concerns must be accounted for, including coverage error, sampling error, measurement error, and nonresponse error. The *coverage error* suggests that all individuals of the population who were intended to be studied were not in the sample (e.g., a study counting the victims of property crimes fails to include victims of auto thefts). *Sampling error* is unavoidable as it is the natural error that accumulates when using a sample and not the whole population, which is normally set at 5% in the social sciences (e.g., for the auto theft example above, the population could have 2% to 12% of auto thefts because of the 5% of sampling error). The *nonresponse error* occurs when respondents have failed to respond and nonrespondents systematically differ from respondents (e.g., respondents have an average age of 36 years, but nonrespondents have an average age of 20 years). Finally, *measurement error* suggests that data collection is not accurate because of the way the researcher operationally defined the variables of interest (e.g., the definition for victims of rape more accurately describes sexual harassment). Thus, to count victims properly, samples and measurement must be carefully designed to decrease limitations and methodological concerns.

Suggested Improvements and Refinements

Irrelevant of the inability to detect the absolute number of victims in the United States, improvements can be suggested to allow for data to be more representative of victimization. First, more offenses could be regularly counted in the UCR Program and NCVS to include less serious offenses such as vandalism. Second, the NCVS could expand by different collection methods (e.g., mail surveys) or samples (e.g., juveniles, college students, homeless, and prison inmates) to allow previously unexamined individuals to be included into NCVS. Additionally, a mixed-method approach could be used to check the reliability and validity of data collection methods. Finally, more attention could be brought to cultural differences in the population of the United States to ensure that respondents understand all terms being used.

METHODOLOGICAL ISSUES IN EVALUATING EFFECTIVENESS OF CRIME PREVENTION

Studies evaluating the effectiveness of crime prevention vary in methodological quality, and the most weight should be given to the best studies. It is essential to develop methodological quality standards for evaluation research that can be understood and easily used by scholars, practitioners, policy makers, the mass media, and systematic reviewers.

Discussions about methodological quality standards, and about inclusion and exclusion criteria in systematic reviews, are inevitably contentious because they are perceived as potentially threatening by some evaluation researchers. People whose projects are excluded from systematic reviews correctly interpret this as a criticism of the methodological quality of their work. In systematic reviews of the effectiveness of improved street lighting and closed-circuit television (CCTV) by David Farrington and Brandon Welsh, referees considered that the excluded studies were being "cast into outer darkness."

Methodological quality standards are likely to vary according to the topic being reviewed. For example, because there have been many randomized experiments on family-based crime prevention, it would not be unreasonable to restrict a systematic review of this topic to the gold standard of randomized experiments. However, no randomized experiments have been designed to evaluate the effect of either improved street lighting or CCTV on crime. Therefore, in systematic reviews of these topics by Farrington and Welsh, the minimum methodological standard for inclusion required before and after measures of crime in experimental and comparable control areas.

This standard was also set as the minimum design that was adequate for drawing valid conclusions about “what works” in the book *Evidence-Based Crime Prevention* by Lawrence Sherman and his colleagues, which was based on the Maryland Scientific Methods Scale (SMS). An important issue is to what extent it is desirable or feasible to use a methodological quality scale to assess the quality of evaluation research and as the basis for making decisions about including or excluding studies in systematic reviews. And if a methodological quality scale should be used, which one should be chosen?

Methodological Quality Criteria

According to Thomas Cook and Donald Campbell, methodological quality depends on four criteria: statistical conclusion validity, internal validity, construct validity, and external validity. According to William Shadish and his colleagues, “validity” refers to the correctness of inferences about cause and effect. From the time of John Stuart Mill, the main criteria for establishing a causal relationship have been that (1) the cause precedes the effect, (2) the cause is related to the effect, and (3) other plausible alternative explanations of the effect can be excluded. The main aim of the Campbell validity typology is to identify plausible alternative explanations (threats to valid causal inference) so that researchers can anticipate likely criticisms and design evaluation studies to eliminate them. If threats to valid causal inference cannot be ruled out in the design, they should at least be measured and their importance should be estimated.

Descriptive validity, or the adequacy of reporting, has been added as a fifth criterion of the

methodological quality of crime prevention research. To complete a systematic review, it is important that information about key features of the evaluation be provided in each research report. The CONSORT statement specifies rules for the reporting of randomized trials in medicine, but there is no equivalent specification for crime prevention evaluation research.

Statistical Conclusion Validity

Statistical conclusion validity is concerned with whether the presumed cause (the intervention) and the presumed effect (the outcome, usually crime or offending) are related. Measures of effect size and their associated confidence intervals should be calculated. Statistical significance (the probability of obtaining the observed effect size if the null hypothesis of no relationship were true) should also be calculated, but in many ways, it is less important than the effect size. This is because a statistically significant result could indicate a large effect in a small sample or a small effect in a large sample.

The main threats to statistical conclusion validity are insufficient statistical power to detect the effect (e.g., because of small sample size) and the use of inappropriate statistical techniques (e.g., where the data violate the underlying assumptions of a statistical test). Statistical power refers to the probability of correctly rejecting the null hypothesis when it is false. Other threats to statistical conclusion validity include the use of many statistical tests (in a so-called fishing expedition for significant results) and the heterogeneity of the experimental units (e.g., the people or areas in experimental and control conditions). The more variability there is in the units, the harder it will be to detect any effect of the intervention.

Internal Validity

Internal validity refers to the correctness of the key question about whether the crime prevention method really did cause a change in the outcome, and it has generally been regarded as the most important type of validity. In investigating this question, some kind of control condition is essential to estimate what would have happened to the experimental units (e.g., people or areas) if the

intervention had not been applied to them—termed the *counterfactual inference*. Experimental control is usually better than statistical control. One problem is that the control units rarely receive no treatment, but instead, they typically receive the usual treatment or some kind of treatment that is different from the experimental intervention. Therefore, it is important to specify the effect size “compared with what?”

The main threats to internal validity were identified by Cook and Campbell but often do not seem to be uniformly well known:

Selection—the effect reflects preexisting differences between experimental and control conditions.

History—the effect is caused by some event occurring at the same time as the intervention.

Maturation—the effect reflects a continuation of preexisting trends (e.g., in crime rates or in normal human development).

Instrumentation—the effect is caused by a change in the method of measuring the outcome.

Testing—the pretest measurement causes a change in the posttest measure.

Regression to the Mean—where an intervention is implemented on units with unusually high scores (e.g., areas with high crime rates), natural fluctuation will cause a decrease in these scores on the posttest, which may be mistakenly interpreted as an effect of the intervention. The opposite (an increase) happens when interventions are applied to low crime rate areas or low scoring people.

Differential Attrition—the effect is caused by differential loss of units (e.g., people) from experimental compared with control conditions.

Causal Order—it is unclear whether the intervention preceded the outcome.

In addition, there may be interactive effects of threats. For example, a selection-maturation effect may occur if the experimental and control conditions have different preexisting trends, or a selection-history effect may occur if the experimental and control conditions experience different historical events (e.g., where they are located in different settings).

In principle, a randomized experiment has the highest possible internal validity because it can rule out all these threats, although in practice differential attrition may still be problematic. Randomization is the only method of assignment that controls for *unknown* and *unmeasured* confounders as well as those that are known and measured. The conclusion that the intervention really did cause a change in the outcome is not necessarily the final conclusion. It is desirable to go beyond this and to investigate links in the causal chain between the intervention and the outcome, the dose-response relationship between the intervention and the outcome, and the validity of any theory linking the intervention and the outcome.

Construct Validity

Construct validity refers to the adequacy of the operational definition and measurement of the theoretical constructs that underlie the intervention and the outcome. For example, if a project aims to investigate the effect of interpersonal skills training on offending, did the training program really target and change interpersonal skills and were arrests a valid measure of offending? Whereas the operational definition and measurement of physical constructs such as height and weight are not contentious, this is not true of most criminological constructs.

The main threats to construct validity center on the extent to which the intervention succeeded in changing what it was intended to change (e.g., to what extent there was treatment fidelity or implementation failure) and on the validity and reliability of outcome measures (e.g., how adequately police-recorded crime rates reflect true crime rates). Displacement of offending and diffusion of benefits of the intervention should also be investigated. Other threats to construct validity include those originating from a participant's knowledge of the intervention and from problems of contamination of treatment (e.g., where the control group receives elements of the intervention). To counter the Hawthorne effect, it is acknowledged in medicine that double-blind trials are needed, where neither doctors nor patients know about the experiment. It is also desirable to investigate interaction effects between different interventions or different ingredients of an intervention.

External Validity

External validity refers to the generalizability of causal relationships across different persons, places, times, and operational definitions of interventions and outcomes (e.g., from a demonstration project to the routine large-scale application of an intervention). It is difficult to investigate this within one evaluation study, unless it is a large-scale, multisite trial. External validity can be established more convincingly in systematic reviews and meta-analyses of numerous evaluation studies. Shadish and his colleagues distinguished generalizability to similar versus different populations, for example, contrasting the extent to which the effects of an intervention with males might be replicated with other males as opposed to the extent to which these effects might be replicated with females. The first type of generalizability would be increased by carefully choosing random samples from some population as potential (experimental or control) participants in a crime prevention evaluation.

The main threats to external validity listed by Shadish and his colleagues consist of interactions of causal relationships (effect sizes) with types of persons, settings, interventions, and outcomes. For example, an intervention designed to reduce offending may be effective with some types of people and in some types of places but not in others. A key issue is whether the effect size varies according to whether those who carried out the research had some kind of stake in the results; for example, if a project is funded by a government agency, the agency may be embarrassed if the evaluation shows no effect of its highly trumpeted intervention. Boundary conditions may exist within which interventions do or do not work or “moderators” of a causal relationship in the terminology of Reuben Baron and David Kenny. Also, mediators of causal relationships (links in the causal chain) may be effective in some settings but not in others. Ideally, theories should be proposed to explain these kinds of interactions.

Descriptive Validity

Descriptive validity refers to the adequacy of the presentation of key features of an evaluation in a research report. Systematic reviews of the effectiveness of crime prevention methods can only be carried out satisfactorily if the original evaluation

reports document key data on issues such as the number of participants and the effect size. A list of minimum elements to be included in an evaluation report would include at least the following:

- Design of the study: How were units allocated to experimental or control conditions?
- Characteristics of units and settings (e.g., age and gender of individuals as well as sociodemographic features of areas).
- Sample sizes and attrition rates.
- Causal hypotheses to be tested, and theories from which they are derived.
- The operational definition and detailed description of the crime prevention method (including its intensity and duration).
- Implementation details and program delivery personnel.
- Description of what treatment the control condition received.
- The operational definition and measurement of the outcome, before and after the intervention.
- The reliability and validity of outcome measures.
- The follow-up period after the intervention.
- Effect size, confidence intervals, statistical significance, and statistical methods used.
- How independent and extraneous variables were controlled so that it was possible to disentangle the impact of the intervention, or how threats to internal validity were ruled out.
- Who knows what about the intervention.
- Conflict of interest issues: Who funded the intervention and how independent were the researchers?

It would be desirable for professional associations, funding agencies, journal editors, and/or the Campbell Collaboration to get together to develop a checklist of items that must be included in all research reports on impact evaluations.

The Maryland Scientific Methods Scale

The most influential methodological quality scale in criminology is the Maryland SMS, which was developed by Sherman and his colleagues for large-scale reviews of what works or does not work in preventing crime. The main aim of the SMS is to communicate to scholars, policy makers, and practitioners in the simplest possible way that studies

evaluating the effects of criminological interventions differ in methodological quality. The SMS was largely based on the ideas of Cook and Campbell.

In constructing the SMS, the main aim was to devise a simple scale measuring internal validity that could be communicated easily. Thus, a simple 5-point scale was used rather than a summation of scores (e.g., from 0 to 100) on several specific criteria. It was intended that each point on the scale should be understandable, and the scale is as follows:

Level 1: Correlation between a prevention program and a measure of crime at one point in time (e.g., “areas with CCTV have lower crime rates than areas without CCTV”).

This design fails to rule out many threats to internal validity and fails to establish causal order.

Level 2: Measures of crime before and after the program, with no comparable control condition (e.g., “crime decreased after CCTV was installed in an area”).

This design establishes causal order but fails to rule out many threats to internal validity. Level 1 and Level 2 designs were considered inadequate and uninterpretable by Cook and Campbell.

Level 3: Measures of crime before and after the program in experimental and comparable control conditions (e.g., “crime decreased after CCTV was installed in an experimental area, but there was no decrease in crime in a comparable control area”).

This was considered to be the minimum interpretable design by Cook and Campbell, and it is regarded as the minimum design that is adequate for drawing conclusions about what works in the book *Evidence-Based Crime Prevention* by Sherman and his colleagues. It rules out many threats to internal validity, including history, maturation/trends, instrumentation, testing effects, and differential attrition. The main problems with it center on selection effects and regression to the mean (because of the nonequivalence of the experimental and control conditions).

Level 4: Measures of crime before and after the program in multiple experimental and control units, controlling for other variables that influence crime (e.g., “victimization of premises under CCTV surveillance decreased compared to victimization of control premises, after controlling for features of premises that influenced their victimization”).

This design has better statistical control of extraneous influences on the outcome and, hence, deals with selection and regression threats more adequately.

Level 5: Random assignment of program and control conditions to units (e.g., “victimization of premises randomly assigned to have CCTV surveillance decreased compared to victimization of control premises”).

Providing that a sufficiently large number of units are randomly assigned, those in the experimental condition will be equivalent (within the limits of statistical fluctuation) to those in the control condition on all possible extraneous variables that influence the outcome. Therefore, this design deals with selection and regression problems and has the highest possible internal validity.

A New Methodological Quality Scale

Although the SMS, like all other methodological quality scales, can be criticized, it has the virtue of simplicity. It can be improved, but at the cost of simplicity. It does seem useful to use some kind of index of methodological quality to communicate to scholars, policy makers, and practitioners that not all research is of the same quality and that more weight should be given to higher quality crime prevention evaluation studies. It also seems highly desirable for funding agencies, journal editors, scholarly associations, and/or the Campbell Collaboration to get together to agree on a measure of methodological quality that should be used in systematic reviews and meta-analyses in criminology. A similar measure should also be used in systematic reviews of studies of the causes of offending (see Murray, Farrington, & Eisner, 2009).

David Farrington's suggestion, put forward tentatively to stimulate discussions, is that a new

methodological quality scale might be developed based on five criteria:

1. Internal validity
2. Descriptive validity
3. Statistical conclusion validity
4. Construct validity
5. External validity

Farrington has placed the criteria in order of importance, at least as far as a systematic reviewer of impact evaluations is concerned. Internal validity—demonstrating that the intervention caused an effect on the outcome—is surely the most important feature of any evaluation research report. Descriptive validity is also important; without information about key features of research, it is hard to take account of the results in a systematic review. In contrast, information about the external validity of any single research project is the least important to a systematic reviewer, because the main aims of a systematic review and meta-analysis include establishing the external validity or generalizability of results over different conditions and investigating factors that explain heterogeneity in effect sizes among different evaluation studies.

Conclusion

It is important to develop methodological quality standards for crime prevention evaluation research that can be used by systematic reviewers, scholars, policy makers, the mass media, and the general public in assessing the validity of conclusions about the effectiveness of interventions in reducing crime. Hopefully, the development of these standards will help to upgrade the quality of evaluation research. All research should not be given equal weight, and criminal justice policy should be based on the best possible evidence. The main conclusion is that new methodological quality scales should be developed, based on statistical conclusion validity, internal validity, construct validity, external validity, and descriptive validity.

MINNEAPOLIS DOMESTIC VIOLENCE EXPERIMENT AND REPLICATION

Appropriate police response is a critical component of any attempt to control the problem of domestic violence. Historically, however, law enforcement agencies found the determination of what constituted an appropriate response to be somewhat challenging. As a result, clear, consistent policies regarding the handling of domestic violence calls were rare. Most police officers relied on their discretion and handled domestic calls on a case-by-case basis. The *Minneapolis Domestic Violence Experiment*, conducted by Lawrence Sherman and Richard Berk for the Police Foundation, provided evidence that clearly indicated that one approach (i.e., the arrest of the aggressive party) was most effective in reducing future involvement in domestic violence. Consequently, law enforcement agencies across the United States adopted policies mandating arrest in the event of a domestic incident. This entry describes the Minneapolis Domestic Violence Experiment and its results, discusses attempts to replicate the study, and examines its implications for long-term policy regarding law enforcement response to domestic violence.

The Study

Historical Background

In the late 1960s, some evidence was produced that suggested that a nonpunitive law enforcement approach to domestic violence involving the use of psychology might be more effective than traditional approaches in reducing additional violent incidents. However, by the late 1970s, both law enforcement and victim advocates began to question the effectiveness of this approach. Consequently, states began to pass legislation that allowed officers to arrest suspects in domestic violence calls, even when the officers themselves

had not witnessed the domestic violence or when no visible evidence was found that a felony had been committed. This movement was largely a response to the need to provide better protection for victims of domestic assault. Evaluation of this stronger approach to determine whether it did, in fact, better serve victims was the next logical step.

In 1980, the Police Foundation received funding from the National Institute of Justice to evaluate the deterrent effect of arrest in cases of domestic violence. Sherman and Berk obtained permission from the Minneapolis Police Department to conduct the study, which commenced in 1981.

Research Design

The study was conducted using classic experimental design. Eligible domestic violence calls occurring during the study period were randomly assigned to one of three police responses: (1) arrest, (2) separation of the parties for a period of 8 hours, or (3) advising in any way deemed appropriate by the officer. Random assignment occurred at the point in time in which the call was determined to be eligible. Eligible calls had the following characteristics: There was probable cause to arrest for misdemeanor domestic assault within the last 4 hours, the victim and offender were clearly defined, no valid order of protection was currently in force, the victim did not insist that the offender be arrested and was not seriously wounded, the officer was not assaulted, and there was no immediate risk of additional violence if an arrest was not made. Each officer was provided with a set of randomly assorted, color-coded report forms that determined the action to be taken in an eligible call. Ineligible calls were handled by officers according to their discretion.

The experiment began on March 17, 1981, and ended on August 1, 1982. During that time period, data were collected on 314 eligible domestic violence calls. The data suggested that the experiment was largely implemented as designed. An arrest was made in nearly all of the cases in which arrest was the assigned response (99%). The percentages were somewhat lower for the calls in which separation or advising was the assigned response, 73% and 78%, respectively.

After the initial encounter with the police, biweekly follow-up interviews were conducted with the victims for a period of 6 months. This portion of the experiment was less successful than the researchers would have liked. The completion rate for the initial interview was only 62%, and only 49% of the victims completed all 12 follow-up interviews. The interviews were supplemented with police reports of repeat domestic violence committed by the suspect during the 6-month follow-up period.

Findings

The results of the experiment were dramatic. Data from both police records and victim interviews indicated that arrest was the most effective option. In fact, arrest reduced the rate of subsequent assaults by nearly 50%. Moreover, arrest was the most effective police action regardless of the suspect's race, employment status, educational level, criminal history, or the length of confinement upon arrest. Furthermore, although there is strong evidence in favor of arrest in most domestic violence cases, the authors were careful to indicate that the evidence does not suggest that a mandatory arrest policy would necessarily be the best approach to the problem.

Results regarding the separation and advisement options were mixed. Official records suggested that separation was the worst option, whereas the interview data indicated that offenders who were advised were the most likely group to reoffend.

Limitations

Like all studies, the Minneapolis Domestic Violence Experiment was limited in ways that may have had an impact on the ability of the researchers to draw valid conclusions. As mentioned, the study was not implemented exactly as designed in that not all of the calls were handled as specified in the color-coded report forms. Although arrest was carried out in nearly all of the cases in which it was required, compliance with the separation and advisement options was not complete. The researchers believed that the lesser compliance in the latter two options was caused by a lack of cooperation from the suspects, which led officers to fall back

on arrest as a last resort. They argued that using arrest as a fallback position should have made arrest *less* likely to be the most effective option, because more of the arrested suspects would have been uncooperative. The fact that arrest turned out to be the most effective police action is a testament to the power of this response.

It is also possible that officers did not follow the randomization system. That is, officers may have used their discretion to determine which of the three response options were most appropriate in a particular case and then pulled the report sheet that fit their decision. In such a case, random assignment would not have occurred, thereby undermining the ability of the researchers to compare the data from the three experimental groups. Unfortunately, it is impossible to determine the extent to which officers may have failed to follow the experimental process.

Another issue is the fact that most of the domestic calls in the study were handled by a relatively small number of officers. Three officers produced 28% of the cases, and 200 of the 314 cases were produced by only 12 officers. It is clear that not all officers in the Minneapolis Police Department were willing to participate in the study. However, the researchers believed that the lack of participation on the part of officers did not have a significant effect on the results produced by the study, because each officer's cases were randomly assigned to the treatment conditions. Consequently, lack of participation by any given officer would not have affected the random assignment and thus should not have had a significant impact on the results produced by the study.

The small size of the final sample for which interview data are available (fewer than 100 cases) is also a potential threat to the validity of the study. Often, a small sample size is an indication that the experimental groups are not as comparable as they should be. As a result, the findings may not hold true in the general population. However, the researchers pointed out that this limitation may not be as serious as it first seems. Although many victims either refused to complete the interviews or could not be located to do so, the proportion of victims in each group completing the interview process was approximately the same. This fact rules out the possibility that victims whose aggressors were arrested may have

been intimidated by the suspects into reporting less violence.

Replications of the Experiment

It is well known that the results of one study alone are not definitive proof that the hypotheses are correct. Therefore, it is good scientific practice for research to be replicated in other sites in order to determine whether the relationships found in the original research will also be supported in different places and under varying conditions. This is the process by which scientific knowledge is developed.

It is especially important to replicate studies when the results of the research may have a substantial impact on policy, as in the case of the Minneapolis Domestic Violence Experiment. Therefore, it is no surprise that the study was repeated in several sites. This section examines these additional studies, particularly those studies that were part of the Spouse Abuse Replication Project (SARP).

Nonexperimental Replications

The first attempts to replicate the results of the Minneapolis Domestic Violence Experiment involved reanalyzing the original data. As might be expected, these analyses consistently found a deterrent effect caused by arrest. However, the strength and nature of that relationship varied depending on the source of the data (victim vs. official records) and the length of time between arrest and the interview.

Studies also employed statistical analyses of police records in numerous jurisdictions in order to determine whether arrest resulted in a reduction of reported violence. These studies consistently found that arrest had a deterrent effect. However, some of these studies found that the deterrent effect might be more complex than suggested by the findings of the original study.

Spouse Abuse Replication Project

Research Design

SARP replicated the Minneapolis Domestic Violence Experiment in five sites around the country: Charlotte, Dade County, Colorado Springs,

Milwaukee, and Omaha. All five studies involved a classic experimental design similar to that employed in the original study. However, the project leaders felt that the original design was flawed in ways that should be corrected in the replications. Consequently, the replications differed from the original study in the following ways:

1. Officers determined whether a case was eligible to be included in the experiment prior to receiving randomized instructions as to how to proceed. In the Minneapolis study, officers carried color-coded report forms that had been randomly mixed prior to their receipt by the officer. The replication researchers believed that completing the random assignment after the officer had determined the eligibility of the case would prevent officers from ignoring experimental protocols.
2. Victim interviews were conducted twice. The first interview occurred within a month of the incident, and the second was conducted at the end of 6 months. The original experiment attempted to interview victims by phone every 2 weeks during the study period. The leaders of the replication believed that the large number of interviews may have resulted in the low number of victims who actually completed the interview process.
3. The measures of repeated aggression on the part of the suspect were more sophisticated. The researchers in the replication recognized that domestic violence may be more complex than simply whether the suspect repeated the behavior. Consequently, several measures of aggression were employed.
4. Arrest was compared with seven different police interventions in recognition of the broad range of alternative actions police officers might take in any given situation.
5. A set of common measures about suspects, victims, treatments, and outcomes was employed to enhance uniformity across the experimental sites.

Across the six replication sites, data were collected on 4,032 incidents of domestic violence. Response rates were high across all sites. Nearly

63% of the victims completed both follow-up interviews.

Findings

Initial analyses of the SARP studies found mixed results. Only Dade County reported a deterrent effect associated with the arrest option, based on analyses of police records. Colorado Springs and Dade County found similar results in the victim interview data, but both sites had lower response rates than the other four locations. It is possible that the result might be a sampling artifact. Omaha, Charlotte, and Milwaukee found that although arrest seemed to deter offenders at first, over time arrest actually resulted in an escalation of the violence committed against the victim.

Three sites (Milwaukee, Colorado Springs, and Omaha) discovered that the effects of arrest may vary with the characteristics of the offender. Data in all three cities indicated that employment status is an important factor. Employed suspects were less likely to repeat the offense, whereas unemployed suspects became more violent. In addition, Milwaukee found similar results for marital status. Arrest was less successful when the suspect was unmarried. In fact, unemployed, unmarried suspects were the most likely group to escalate violence after arrest.

It is unclear why the findings from these studies differed so much from each other and from those reported in the Minneapolis Domestic Violence Experiment. One potential explanation lies in differences in the demographic characteristics of the sites. It is true that the race of the suspects did vary a lot across the sites, although not consistently across the sites that did or did not find a deterrent effect. Other characteristics thought to be important were consistent across the sites, however, limiting the utility of this explanation.

Although the SARP project leaders strove for consistent implementation of the experiment, it is also possible that the protocols were not exactly the same across sites. For instance, only Milwaukee kept precise records regarding how long a suspect was held after arrest. Omaha relied on informal polls of officers to measure this variable. Other sites defined the term differently. Consequently, trying to compare conclusions about the effect of length of time in custody from each of the sites is

like trying to compare apples and oranges. This effect may be compounded when comparing the results with the Minneapolis study, which clearly employed different protocols. Some support for this explanation is found in a later analysis of the SARP data across all five sites, which used only those measures that were consistently defined across all locations. The analysis found that victim interviews indicated a reduction in aggression associated with arrest. However, the analysis could not find similar results in the official data. Although a reduction in aggression seemed to occur after arrest in the official data, the relationships were not statistically significant, leaving the question open for additional research.

It is also possible that the effect of specific police actions on future violent incidents is more site specific than generally expected. That is, it is possible that domestic violence is not only a more complex phenomenon than originally expected, but it may also vary across different social contexts. If so, the lack of consistency in the results would reflect true differences across the various locations rather than the limitations of the study designs. That would suggest that a national policy of arrest in domestic violence cases would not be wise.

Policy Implications

The effect of the Minneapolis Domestic Violence Experiment on law enforcement policy is somewhat unclear. Clearly, states were already moving toward the enactment of legislation, giving police more authority to make arrests in domestic violence cases prior to the experiment. Thus, it is impossible to say that the results of the study were the foundation of this movement. However, it is also clear that for many police departments, the experiment provided the evidence they required to adopt a proarrest policy. A 1984 poll of police departments found that more than a third of the respondents indicated that the published results of the study were instrumental in their decision to enact such a policy. Moreover, the 1984 Attorney General's Task Force on Family Violence relied on the experiment in its recommendation that arrest be the preferred policy in these cases. Therefore, it is certain that the experiment played a significant role in the development of this policy across the nation.

Yet, it is also certain that what we learned from the study is not as clear as it originally seemed. The fact that replications of the study were not able to produce consistently the same results as the Minneapolis experiment is problematic. Furthermore, the finding in some sites that arrest might actually result in an escalation of the violence is troubling, particularly given the current situation in which pro-arrest policies have been adopted in virtually all law enforcement agencies around the country. Given the politically sensitive nature of this issue, it would be difficult, if not impossible, at this juncture to modify the policies in such a way as to encourage officers to tailor their approach to the specific situation without leaving victims feeling as if they were abandoned by law enforcement.

Perhaps the best lesson to be learned from the Minneapolis Domestic Violence Experiment and its replications is that a single study should not serve as a primary basis for policy decisions. In this instance, a perfect confluence of events—the right study results combined with the right political and social context—led to policy that may or may not be the best solution to the problem. The wisest course of action would have entailed waiting until the study had been replicated and the findings had been demonstrated to be supported consistently prior to making a policy decision.

MISSING, EXPLOITED, AND MURDERED CHILDREN

Children are society's weakest and most vulnerable group, and crimes perpetrated against them—such as kidnappings, sexual exploitation, and murder—evoke strong feelings in most of the public. Hence, a study of the serious and multifaceted problem of missing, exploited, and murdered children is vital for law enforcement, society at large, and the victims themselves.

Risk Factors

Victimology has become a large subsection of criminology, and many would say its own discipline. Lawrence Cohen and Marcus Felson, in their famous routine activities theory, stated that all that was needed for victimization to take place (and this is especially germane to many crimes against children) is an available target, a lack of a capable guardian, and the presence of a motivated offender. In many crimes against children, of course, this is the case. Adding to his original routine activities work, Cohen sought to establish a theoretical link between routine activities theory and both lifestyle and proximity theories. Cohen looked at the following five factors that he felt might explain victimization:

1. The exposure of victims to those who may offend against them.
2. The presence of a crime-preventing guardian.
3. The proximity between the residences of the potential victims and the potential offenders.
4. The “attractiveness” of targets.
5. The definitions of any given crime and the difficulty of that level of crime.

When looking at victimology and children, it is important to consider that child molestation is probably the most common crime against the person in the United States today, and 25% of girls and 10% of boys (it is estimated) will experience some kind of sexual abuse during their lifetime; in addition, girls are more likely to be abused from inside the family and boys are more likely to be abused from individuals outside the family.

Recent research has shown that most missing children are not the result of custodial disagreements resulting in kidnapping by parents. Rather, common causes are as follows, in order from most frequent to least frequent:

1. Runaways
2. Family abductions
3. Lost, injured or otherwise missing children
4. Nonfamily abductions (in these cases, the child is at greatest of injury or death)

One study developed a risk factor analysis for victimization in girls and presented the following as potential predictors:

1. Living with a stepfather
2. Living without a biological mother
3. Not close to mother
4. Mother never finished high school
5. Sex-punitive mother
6. No physical affection from (biological) father
7. Family income under U.S.\$10,000 (in 1980 dollars; U.S.\$26,000 in 2006 dollars)
8. Two friends or fewer in childhood

This study found that if a girl had none of the above predictors, her chance of victimization was virtually zero; if a girl had five of these predictors in her life, then the chance of victimization rose to 66%.

Scale, Nature, and Typology

To study the issue of missing, exploited, and murdered children, it is important to quantify its

nature and size. According to the Department of Justice statistics, 797,500 children under the age of 18 years were reported missing in a 1-year period; family members abducted 203,900 of these, non-family abductions accounted for 58,200, and 115 children were the victims of *stereotypical kidnapping*. The remaining missing children were due to benign reasons not related to a criminal act. Stereotypical kidnappings are defined as involving someone the child does not know or someone of slight acquaintance, who holds the child overnight, transports the child 50 miles or more, kills the child, demands ransom, or intends to keep the child permanently. One study found that cases of abducted and missing children being murdered were rare; approximately 40 to 150 such incidents occurred each year. This figure represents less than half a percent of all discovered murders carried out each year. A more disturbing finding was that 76.2% of those children not discovered safely within 3 hours of abduction had been murdered within that time.

The 76.2% figure is based on data garnered from nonfamily-abducted children; however, this figure is posited to be much lower in "family abduction" situations where the child is generally taken by another parent in situations of custodial disagreement. Family abduction can be severely psychologically damaging to the child abductee as he or she may be told by the familial kidnapper that the other parent no longer wants or cares for them. In addition, the child may be forced to live life as a fugitive never settling in a residence or school, thereby limiting the normal developmental and social skills to be achieved.

Child pornography, a form of sexual exploitation, is defined by Stephen T. Holmes and Ronald M. Holmes as underage children who have been used in various media to arouse those who chose to view them. Holmes and Holmes also discovered in their extensive research that when pedophiles are arrested and their belongings are inventoried, there is almost always some type of child pornography present. Children can become involved in the production of this material in a variety of ways. Sometimes parents are involved in "sporting clubs," which are groups of like-minded individuals who share indecent photographs or videos of their children among each other. Some of these victims engage in pornographic acts because they

are intimidated by authority figures such as a parent, teacher, or relative. LeRoy Schultz discovered another method to involve children in these acts; couples were taking "street kids," some as young as 6 months, into their home, ostensibly to care for them, and then forced these children either into child pornography or prostitution. Furthermore, the Illinois Legislative Investigative Committee in 1980 found a summer camp being used as a front for enticing children into child pornography.

Empirical Analysis

According to some studies, there may well be more than 30,000 children involved in the production of child pornography, and of those 30,000, as many as 10% (under the age of 14 years) were in the greater Los Angeles area. Some question the accuracy of many of these studies and want to approach the problem from a qualitative as opposed to a mainly quantitative issue of the problem. Holmes and Holmes report that many of these studies found some common characteristics in children who had become involved and victimized by the phenomenon of child pornography. These are as follows:

1. Involvement in childhood prostitution
2. Runaway
3. Product of a broken home
4. Typical age between 8 and 17 years
5. Underachiever in school or at home
6. No strong moral or religious affiliation
7. Poor social development
8. Parents physically or psychologically absent

In their more quantitative methodology in Kentucky, interviewing juveniles who had self-reported involvement in child pornography, Holmes and Holmes also discovered that less than 15% of the Kentucky victims had parents who were married and that about 20% reported some form of family discord, lack of a loving environment, and a remoteness from both parents and siblings (if any were present). All the children questioned used alcohol or drugs, and approximately 80% stated that they were runaways.

As repugnant as the loss, kidnapping, or sexual exploitation may be, surely another terror in the hearts of most parents is that of their child being the victim of a kidnap-homicide.

In the empirical analysis of Holmes and Holmes, the victimology involved in kidnap-homicide was broken into groups:

1. Females represented 69% of the victims, whereas males represented 31%.
2. By age, the highest at risk group was 12 to 14 years (38%). Half that figure, 19%, was made up of 0- to 5-year-olds.
3. Whites and blacks were overrepresented in victimization, whereas Hispanics were underrepresented.
4. Seventy-one percent of the perpetrators were strangers as opposed to "slight acquaintances."
5. In 86% of the cases, the perpetrator was male.
6. Only 11% of the identified perpetrators were more than 40 years of age as opposed to 57% being between 20 and 39 years of age.

Katherine Brown and her colleagues discovered females to be greatly overrepresented in child murder than in all murders (38%–74%) and males to be underrepresented in child murders than in all murders (26%–62%). They also found that, contrary to popular belief, children 6 years old and younger represented only 10% of all child murders. The idea of street kids being more vulnerable to such attacks was also debunked by this study as the friends of the victims described more than two thirds of them as "normal," 16.9% as "street-kids," and 13% as "runaways." Females represented 55% of all child murders as opposed to 38% of all murders (an overrepresentation); males represented 45% of all child murders and 62% of all murders.

According to the Department of Justice, many children had the misfortune to encounter a motivated offender randomly (i.e., stranger). In all, 50.5% were abducted in urban areas and 47.2% were incapacitated via direct physical assault. Strangulation was the leading cause of death in 33.2% of the cases; 23.9% were caused by blunt force trauma; and 23.3% by stabbing or cutting.

Initiatives

Among the most successful initiatives is the Child Abduction and Serial Murder Investigative Resource Center, which is run under the auspices of the Violent Criminal Apprehension Program through the Federal Bureau of Investigation. In addition, the number of states that use AMBER (America's Missing: Broadcast Emergency Response) Alerts is increasing. This program recovered 90 children in 2003 alone. In a 2004 Department of Justice press release, John Ashcroft stated, "When a young child is taken by the violent and predatory, we cannot stand idle. We demand accountability. We demand justice. . . . Today is the day to remember those who are gone, but whose imprint on our lives is still felt. It is a day to reflect on our calling as a free people to forge a nation that protects the lives of the most vulnerable."

MOTOR VEHICLE THEFT

Among the major crime types, auto theft is possibly the most ubiquitous. Motor vehicles are to be found just about anywhere, and as such, they are particularly interesting to crime prevention practitioners and researchers alike. Property crimes—such as those involving vehicles—are often overlooked in planning circles, despite their important impacts on the public perceptions of safety and levels of satisfaction with our respective justice systems.

Definitions

Auto theft is the common term in North America for the taking of a motor vehicle without consent. Subtle, but important, distinctions should be made when attempting to compare auto theft data internationally. Vehicle theft data for both Canada and the United States are similar in counting procedures. Canada, unlike the United States, includes in its motor vehicle theft counts the unauthorized taking of farm and construction equipment; instead, the United States counts these incidents as larcenies. More importantly, each vehicle that is stolen is counted once for both nations, with the exception of thefts from automobile dealerships, which, perhaps curiously, is counted once in the Canadian system. Estimates of the impact of these differences is less than 1%, with the Canadian numbers showing a slight undercounting relative to the U.S. data. England and Wales data are also comparable with their North American counterparts.

Motor vehicle thefts are broken into completed and attempted thefts. Victimization surveys in North America as well as in England and Wales include richer data about household experiences but

not about commercial motor vehicle theft. Such surveys also include a potentially larger set of “vehicles” that may not be captured in police data or in all countries. Vehicle-related thefts are counted separately from successful and attempted thefts of the vehicle itself. As a result, concerns regarding counting develop, as it is often hard to distinguish between a “theft from” and a “theft of” situation where the perpetrator was interrupted in the process of stealing the vehicle. In England and Wales, theft of a motor vehicle is broken into five categories under the heading “offences against vehicles.” The first is similar with the North American experience; this category includes theft and attempted theft, but it requires that the theft be of a permanent nature. Stealing a vehicle for resale or use of parts would be common examples. These forms of theft are more often linked to more or less organized crime groups. This category is the least likely to be recovered, as the vehicles tend to be modified quickly, “parted-out,” and sold. Vehicle theft “rings” often distort or falsify vehicle identification numbers to evade notice or recovery. In some cases, stolen vehicles are moved one or more jurisdictions or even countries to facilitate reuse. The second form involves the unauthorized taking of a vehicle for temporary use or enjoyment (such as “joy riding”). Such vehicles are typically recovered within a short period of time and with few suspects, but those that are known to police tend to be younger males. Aggravated vehicle taking involves dangerous driving or is involved in an accident. The final two forms cover thefts, successful or otherwise, of vehicle contents, and interfering with a motor vehicle, which often includes attempted thefts where intent is not clear regarding permanency.

Trends

National data collected by police and findings from the 2004–2005 International Crime Victimization Survey (ICVS) show declining rates for auto thefts in the United States, England and Wales, Australia, and Canada. These reductions also follow increases of incidents known to the police in the 1960s and 1970s for both North America and England and Wales. Improvements have been made to physical security, such as installation of more sophisticated door and window locks as well as alarm systems. Researchers have noted, however, that despite a

doubling of officially recorded offenses, the general consensus is that better counting and record-keeping procedures on behalf of police and increased willingness of citizens to report victimization experiences account for much of the swing in Uniform Crime Reporting Program rates. It should be noted, however, that despite recent discussions of changing/upgrading licensing and registration protocols, it is not yet clear what empirical benefits might be expected—if any—over current practices.

Like burglary, auto theft is trending downward per capita in police statistics and reported victimization, although as several researchers point out, the costs to its victims remain significant, especially as auto thefts have an inherent risk of accidents occurring during the aftermath of the offense. The 2004–2005 ICVS data suggest that for the 30 reporting nations, approximately 1% of respondents experienced auto theft. Researchers cite improved general advancements in protecting the envelope of vehicles and to better electronic immobilization technologies as the main reasons that these offenses are occurring less frequently than in the past, as these improvements have the greatest impact on crimes of opportunity. Nevertheless, it seems that thieves are adapting to less easily exploitable door locks and immobilizers. Some thieves are using keys obtained fraudulently from car dealers, by finding extra copies of keys inside the home or garage, or even in the car itself. Between 1998 and 2001, for example, the use of keys in England and Wales rose from 7% to 12% of all car thefts, showing that even new vehicles and those fortified with immobilization devices and technology remain vulnerable.

Young males are more likely to steal cars than older males or girls or women of any age. Sophisticated and/or highly skilled vehicle thieves still operate and are thought to be more representative of the “professional,” for-economic-profit, criminal who sends the vehicle to a “chop-shop” where it will be stripped for parts or modified to avoid discovery. In addition to black market demand, more organized thieves target vehicles to assist in the commission of other offenses such as burglaries.

Spatio-Temporal Clustering

Long-term parking facilities, such as parking lots near major commuter transit stations, for example,

serve as attractors for vehicle crime. Targets are plentiful, and car owners are unlikely to return for many hours. Thefts in this setting happen during the day, whereas in residential areas, they tend to occur during the night. Vehicles parked near bars or nightclubs, or at sports venues, are plentiful, easy to assess for target suitability, and often provide enough time to assess likely risks of being caught if an attempt is made.

is a developmental process. Although exceptions exist, most high-rate juvenile and adult offenders initially manifest conduct problems early in life that are recognized by parents, teachers, and peers. These youngsters experience the early onset of delinquent activities and of serious criminal offenses. They are disproportionately at risk of being incarcerated in a juvenile facility or adult correctional institution.

This recognition that the origins of crime extend to childhood and early adolescence has important policy implications. Until recently, treatment programs have largely targeted older juveniles and adults already in the criminal justice system. Findings revealing the childhood roots of crime, however, challenge this exclusive focus on those who already have embarked on a criminal career. Instead, the logic of life-course criminology suggests that at-risk youths can be identified and reformed starting in childhood and early adolescence, with care extending as the youth ages.

Unfortunately, most serious juvenile offenders do not receive meaningful treatment services until they reach the justice system. This gap in the delivery of services to at-risk youngsters has led to a call for the expansion of early intervention programs. Opinion polls show that the public strongly supports such attempts at “child saving.” The more pressing challenge is what programs might be implemented that can intervene with youths who are destined to be entrapped in a life of crime.

Developed in the late 1970s by Scott Henggeler, multisystemic therapy—commonly known by the acronym of MST—is one of the most important early intervention programs that has emerged to address this problem. It is estimated that MST programs serve approximately 10,000 youths annually and can be found in more than 30 states and 11 nations. These programs have been evaluated rigorously, and their effectiveness has been assessed. MST promises to be an important early intervention program aimed at high-risk adolescents for the foreseeable future. The target population includes persistent, violent, or substance-abusing juveniles between the ages 12 and 17 years and their families.

This entry first discusses why MST represented a new paradigm or way of thinking about intervening with at-risk youths. It then explores in

MULTISYSTEMIC THERAPY

Since the late 1980s, scholars have increasingly documented that becoming a predatory offender

more detail what the MST intervention involves. The issues of the effectiveness of MST in reducing wayward behavior and cost-effectiveness as a public policy are also examined. The discussion ends by considering the future of MST.

A New Paradigm

The traditional psychotherapeutic model required troubled youths, and perhaps their parents, to come weekly to an office for an individual session lasting an hour. The length of treatment was open ended and could last months, if not years, on end. Recalcitrant youngsters were candidates for placement in a residential facility. This approach often proved costly, was ineffective in reducing antisocial conduct, and often failed to reach inner-city youths.

Scott Henggeler was part of a community psychology movement that eschewed this individualistic, more psychodynamic approach to counseling wayward adolescents. Instead, he embraced the social-ecological model, which portrays the reciprocal exchange between the individual and familial and community contexts. More concretely, youths not only have individual traits and reside in particular families, but also they are affected by other social systems: peers, schools, and community. In short, they live in multiple systems.

Empirical research has demonstrated that along with individual traits, each of these systems can expose a child or adolescent to criminogenic risk factors that increase the likelihood of law-breaking conduct. For example, a family risk factor might include ineffective parental discipline, a peer risk factor might involve contact with antisocial friends, and a school risk factor might be low achievement. For each troubled youth, the particular set of risk factors underlying his or her misconduct is likely to be unique. The intervention, thus, must be aware of this fact and be flexible enough to address risk factors drawn from different social domains.

Informed by the social-ecological model, MST offered just such an innovative therapeutic paradigm. Again, it is sensitive to the reality that troubled youths are situated in multiple systems that, to a greater or lesser extent, may contribute to their offending. The specifics of this intervention are conveyed in the next section.

The MST Intervention

As Henggeler noted, MST is a holistic intervention that targets the variety of factors that are related to the causes of problem behavior. MST staff members are not office based but deliver services in home or in community settings (e.g., school). Each clinician has a small caseload that is limited to about five families, each of which receives 2 to 15 hours of intervention each week. Recognizing the uncertain timing of crises, clinicians are available 24 hours, 7 days a week. The MST intervention is intended to be intense but also time-limited (about 4 to 6 months), which is a factor that contributes to its cost-effectiveness.

Staff members are given a 5-day orientation regarding MST's treatment model. To ensure quality-of-service delivery thereafter, they receive supervisory visits at least once a week. A special MST expert also consults with the treatment team and provides booster training.

When initiating the intervention, the MST clinician and supervisor take the responsibility to engage or "hook" the youth and family in the treatment. An important task is to diagnose the risk factors or problematic relations that are contributing to the youngster's misbehavior. This might involve persistent conflict with parents, drinking with friends, and truancy. The intervention attempts to build on individual (e.g., high IQ) and system (e.g., a supportive teacher or coach) strengths in a positive way. Services are individualized to meet the unique needs of each troubled youngster. The specific interventions used by clinicians are adapted from empirically supported treatment modalities, such as strategic family therapy, structural family therapy, behavioral parent training, and cognitive behavioral therapies. More broadly, in the *Blueprints for Violence Prevention* series, Henggeler presents the following nine central principles of MST:

1. The primary purpose of assessment is to understand the fit between the identified problems and their broader systemic context.
2. Therapeutic contacts emphasize the positive and use systemic strengths as levers for change.
3. Interventions are designed to promote responsible behavior and to decrease irresponsible behavior among family members.

4. Interventions are present focused and action oriented, targeting specific and well-defined problems.
5. Interventions target sequences of behavior within and between multiple systems that maintain identified problems.
6. Interventions are developmentally appropriate and fit the developmental needs of youth.
7. Interventions are designed to require daily or weekly effort by family members.
8. Intervention effectiveness is evaluated continuously from multiple perspectives, with providers assuming accountability for overcoming barriers to successful outcomes.
9. Interventions are designed to promote treatment generalization and long-term maintenance of therapeutic change by empowering caregivers to address the needs of family members across multiple system contexts.

Effectiveness

Although questions have been raised about the quality of the evidence favorable to MST, a mounting body of evaluation studies exists that suggest that MST may be an effective intervention for a multitude of problem and criminal behaviors. In a meta-analysis of 11 studies conducted by Nicola Curtis, Kevin Rolan, and Charles Borduin, MST was found to reduce criminal behaviors significantly with an average effect size of 0.50. Specifically, MST was associated with a reduction in the number of arrests for all crimes, number of arrests for substance abuse crimes, seriousness of arrests, number of days incarcerated, and self-reported delinquency and drug use.

Studies using randomized experimental designs also provide much support for the effectiveness of MST with serious juvenile offenders. When comparing juvenile offenders placed in MST versus individual therapy, Borduin and his colleagues found that MST was more effective in reducing rearrests than individual therapy. Specifically, 71.4% of the individual therapy youths were rearrested within 4 years, whereas only 26.1% of the MST youths were rearrested.

Not only is MST an effective intervention with serious juvenile offenders, but it is also effective

with juvenile sex offenders. Compared with individual therapy, MST is more effective in reducing rearrests for both nonsexual and sexual offenses. Concerning nonsexual offenses, 25% of the youths treated with MST were rearrested within 3 years, whereas 50% of the youths treated with individual therapy were rearrested. Examining sexual offenses, 12.5% of the MST group was rearrested compared with 75% of the individual therapy group.

Evidence also exists that MST is cost effective. This is an important policy consideration because of the need to show a return of the investment made by the public in an intervention. The cost-effectiveness of MST extends from its demonstrated ability to use a time-limited, community-based intervention to reduce crime among serious offenders who otherwise would have received services for a much longer period or been incarcerated in a residential facility. Henggeler found, for example, that whereas the cost of "usual services" was \$17,769, the cost for MST per offender was \$3,500. More recent studies have shown similar cost savings.

Future Challenges

MST has emerged as an important early intervention program for adolescents at risk of criminal careers. Much of its credibility derives from its fidelity to evidence-based practices. The intervention targets for change empirically established risk factors for crime; MST clinicians use evidence-based intervention treatments; and from its inception, the programs based on MST principles have been subjected to rigorous evaluation by Henggeler and his colleagues.

The special challenge for MST is whether the program can be disseminated widely and still maintain its effectiveness. Evidence exists that when the principles of MST are adhered to closely, the resulting interventions are successful in reducing serious offending and in improving the lives of children and their families. However, the reverse is true as well: Failure to follow MST principles produces ineffective programs. Still, MST has procedures in place to license interventions and to increase the possibility that program integrity will be sustained. If this strategy proves meaningful, MST could serve as a significant

crime prevention resource in communities into the foreseeable future.

MUNCHAUSEN SYNDROME BY PROXY

It is estimated that about 6 million cases of child abuse or neglect occurred in 2006. Although this number is high, many additional incidents of child abuse and neglect go undetected and some forms of abuse are masked by what seem to be common ailments. One such type of child abuse is Munchausen Syndrome by Proxy (MSBP). MSBP is a form of abuse that occurs when a caregiver fabricates or induces an illness in the person being cared for, typically a dependent child. MSBP was first noted in a medical journal, *The Lancet*, in 1977. In this article, Roy Meadow, a pediatrician in the United Kingdom, detailed two case histories of MSBP. The term *Munchausen Syndrome by Proxy* stems from historical accounts of German mercenary officer Baron Karl von Munchausen (1720–1797). He was infamous for telling false stories about his adventures and conquests throughout Europe. Since MSBP is the fabrication of an illness, Munchausen’s name was attached to the behavior.

MSBP is not only difficult to detect, it is equally as puzzling to understand. MSBP may be perpetrated by men or women; however, offenders are most often females in a caregiver role, typically the mother. However, she may be an aunt, au pair, babysitter, or foster parent. Victims are usually the child of the offender, but any child for whom the abuser cares for can fall prey to MSBP. Illnesses that are commonly fabricated include sleep apnea, personality changes, vomiting, seizures, diarrhea, and unconsciousness. MSBP manifests itself through the simulation or production of symptoms, or a combination of both. Simulation of symptoms, a quarter of all cases, involves fabrication about the illness by either the caregiver (particularly for young victims who cannot talk or articulate the problem) or the victim (who may have been coerced into lying). The production of symptoms, about half of all cases, involves purposeful infliction of harm to the victim by the offender. The child may be physically beaten, suffocated, orally poisoned, have his or her blood injected with toxins or medications, or have necessary medications withheld to worsen an already existing medical

problem. In older children, the production of symptoms may result from somatization (i.e., the psychological onset of an illness or physical disturbance). Victims may be taught by the offender to reproduce ailments on demand. About 25% of all cases involve both simulation and production of symptoms.

In cases of MSBP, the caregiver seeks medical attention for the victim's "illness." Victims are often taken to the hospital, and the offender may tell the physician or attending medical personnel that there is no known cause for the child's symptoms. Ensuing physical examinations may yield no visible signs of sickness, results from medical tests and X-rays may be normal, and patients may not respond to medicines or surgeries. Victims who do not respond to a battery of tests may be hospitalized for continued observation. If the physical abuse and production of symptoms has not occurred before the victim was admitted to the hospital because it was feigned, it will likely begin once the victim is admitted so that medical attention and care will continue and the MSBP offender can maintain control over the situation and victim.

Offenders

Offenders are likely to be seemingly normal and attentive parents. They are often well educated, possibly having attained some medical knowledge either formally through school or being self-taught, and may be fluent in medical terminology. Offenders are often knowledgeable about medical procedures and feel comfortable in a medical setting. They may offer advice or suggestions to the physicians and nurses who are trying to determine the type and cause of the child's illness. They will likely welcome or suggest medical tests that may be painful to the child.

Part of the lure for offenders committing MSBP is the attention and sympathy they receive because their child is sick or the recognition and praise from others, including medical staff, for being an attentive and doting mother who cares for the child. Most MSBP occurs as a result of psychological motivations. They assume the role of a sick person through the dependent child, and this fills a psychological need that varies by offender. Many offenders suffer from psychological problems such as low self-esteem or simply loneliness, and they

may thrive on the "martyr" role and attention they receive from the abuse. Perpetrators may meet a need for dependency or symbiosis by victimizing the dependent child. Other possible reasons for the abuse include the perceived need for control over the victim and an outward manifestation of their inability to care appropriately for the child.

The nonoffending parent, often the father, usually has little involvement in the child or family's life. This lack of attention and care toward the mother and children may allow the abuse to occur and may be causally related in some cases. For instance, the offender may commit MSBP to garner the attention they desire from the noninvolved party.

Psychological Factors

Being an MSBP offender does not by definition constitute mental illness, nor is MSBP caused by mental illness because offenders are not psychotic or dissociative from reality when abusing their victims. However, perpetrators may suffer from psychological disorders such as depression, compulsive lying, and/or borderline, narcissistic, histrionic, or avoidant personality disorders. These disorders may contribute to the abuse because they affect normal coping mechanisms. The term used by the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)* for MSBP is Factitious Disorder by Proxy. *DSM-IV* does not classify MSBP as a mental illness. However, it is listed in the manual's appendix as a category requiring more study. The following *DSM-IV* criteria must be met for a diagnosis of MSBP: intentional production or feigning of physical or psychological distress in an individual under the care of the offender, the motivation of the offender is to assume the sick role by proxy, no external incentives exist, and no other disorder better explains the behavior.

Munchausen syndrome, a disorder related to MSBP, occurs when individuals fabricate or induce an illness affecting not another person but themselves. Similar to MSBP, those presenting with Munchausen syndrome desire the attention and sympathy that accompanies treatment for an illness. Munchausen syndrome is considered a mental illness, whereas MSBP is a medical diagnosis. MSBP occurs "by proxy," and offenders do not typically

suffer from Munchausen syndrome. Instead, they project the behavior onto their victims. In doing so, they indirectly assume the role of a sick individual who is purportedly in need of treatment.

Victims and the Effects of MSBP

The victims of MSBP can be either male or female. Age of onset for abuse typically begins shortly after the first birthday, and most victims are younger than 6 years old. Siblings of MSBP victims are at increased risk for abuse because many offenders abuse more than one of their children. As many as 25% of MSBP cases involve more than one victim in the family.

Child victims of MSBP are often prevented by the abuser from engaging in normal contact with people outside the family. Their education may be interrupted because of repeated visits to doctors' offices and hospitals, which can also limit interaction with others. The abuser may often speak for the child or limit the child's relations with peers. Because of the control offenders have over their victims, victims of MSBP may feel more comfortable talking with outsiders (e.g., medical personnel, police, and case workers) when the offender is not around.

Victims of MSBP may suffer physical and psychological damage resulting from the abuse. Psychological manifestations of abuse can appear in the victim such as posttraumatic stress disorder, irritability, aggressiveness, withdrawal, dependency, and depression. Victims may have nightmares, they may be fearful, or their sleep cycles may be disrupted. The victims may learn to accept the illness and symptoms as real, through conditioning, and may learn the art of manipulation themselves. Developmental delays such as immaturity and separation anxiety may also occur. Additionally, children who suffer from any child abuse, not only MSBP, are at increased risk for engaging in violent behavior later in life.

Tragically, victims may even be killed by their abuser. Studies report that the mortality rate for MSBP victims ranges from 9% to about 30%. This wide range shows the difficulty in properly identifying victims of MSBP. The death of a victim may not directly result from homicide, but it may be the result of numerous unnecessary medical procedures having been performed in attempts to pinpoint a cause of the mysterious symptoms. Cases of MSBP

may also be misdiagnosed as sudden infant death syndrome (SIDS). In cases of SIDS, children suddenly die without sufficient explanation, even after a thorough investigation and autopsy, as to why the death occurred.

Identification and Prosecution of MSBP

MSBP is not, in and of itself, a violation of the law. However, in the course of MSBP, many offenders commit acts that are consistent with child abuse. Therefore, investigations into MSBP cases must be handled as a criminal investigation. Suspicion should be heightened if any symptoms that the victim presents upon admission to the hospital disappear or lessen once the caregiver has left the child, or if offenders resist separation from the child. Victims are often unresponsive to treatment or may improve drastically once released from the hospital or removed from the care of the offender. The victim may feel better when the offender is not around—what is known as a positive separation test.

MSBP can go undetected simply because it is difficult to imagine that a mother would place her child in danger. Identification and prosecution of MSBP often requires input from various agencies. This input may include medical personnel, law enforcement and attorneys, child protective services, and social services. Physicians may be the most qualified persons to make a diagnosis of MSBP because they have direct access to the medical records of victims and will have interacted with the caregiver directly when trying to determine the cause of illness. However, the field of medicine typically relies on self-report or parental input to assist in determining the cause of the illness and other medical history.

Such a diagnosis is not obligatory before an arrest can be made. However, sufficient evidence must be gathered before the suspect can be formally charged and arrested. Law enforcement officials must make an evidence-based judgment using profiling techniques and taking into account the suspect's personality and history (including any history of having a similar illness as the child), as well as the physical evidence to support an arrest. Investigators should determine whether there is a history of other children having died while under the care of the suspect. Once sufficient evidence is gathered, MSBP offenders may be charged with

child endangerment, child abuse, child neglect, or homicide if the victim dies as a result of the abuse.

Treatment for Offenders and Victims

MSBP offenders can be resistant to psychotherapy treatment. They frequently deny that they are responsible for any ill-will or abuse toward their victim. However, it has been documented that some perpetrators who were confronted by medical personnel have stopped the abuse. To treat victims effectively, psychologists need to determine baseline measures of emotional and psychological functioning, cognitive ability, and other developmental abilities. Victims need to learn to develop trust and deal with any emotions stemming from the abuse such as anxiety. Also, the self-image of victims may be fractured. They may continue to see themselves as the “sick” child who is in need of attention and medical care. Play therapy among young victims seems promising. If children are removed from the home and placed either with another family member or in child protective services, such as foster care, any visitation should be strictly supervised to prevent additional abuse by the offender.

MUTUAL BATTERY

Mutual battery is a term that is used to describe intimate partners who both use violence against each other. It is a controversial term that disguises many of the complexities of intimate partner violence. *Mutual* implies two equal individuals who inflict the same level and form of injury for the same reasons. *Battery* is a legal term that describes physical assault. Research on intimate partner violence suggests the limitations of each of these terms and of *mutual battery* for understanding and developing effective interventions for intimate partner violence.

Research Findings and Controversies

Much of our knowledge of intimate partner violence is derived from general social surveys. With some variation, these surveys rely on measurement tools, primarily the Conflict Tactics Scale and Conflict Tactics Scale 2, which ask people to report how often they have been victims or perpetrators of violence in their intimate relationships. Across a range of studies, men and women report about equal levels of violence perpetration in their relationships. However, these surveys do not provide data on the context of, and reasons for, violence. Qualitative studies that rely on interviews with victims and perpetrators drawn from agency and clinical samples suggest that the dynamics of intimate partner violence vary depending on the context and motivation for violence. These studies also find that mutual battery is rare and that men are far more likely to engage in intimate partner violence that is part of a pattern of coercive control. Michael Johnson developed a typology of intimate partner violence that addresses the differences in findings between quantitative general surveys and qualitative, nonrandom studies. Johnson argues that the gender symmetry revealed in general surveys describes “situational couple violence.” In this form of intimate partner violence, both members of a couple use violence as a response to a specific conflict. It may be a serious level of violence, but it is not part of a larger pattern of abuse. On the other hand, he describes the primarily male perpetrated violence described in qualitative studies as “intimate terrorism.” This

violence is motivated by a desire to control a partner coercively and is only one strategy in a pattern of abusive behaviors that also includes emotional, verbal, economic, and sexual abuse. Situational couple violence is often termed “mutual battery.” Intimate terrorism may also be mutual, with both partners engaging in violence and coercive control, or what Johnson refers to as “mutual violent control.” However, this form of intimate partner violence is unusual and has not been studied in any depth. The term *mutual battery* does not encourage the kind of nuanced understanding of intimate partner violence that has developed in research and scholarship since the 1990s.

Implications for Policy and Treatment

The institution of mandatory and presumptive arrest policies for intimate partner violence has led to increases in dual arrests of both partners. Law enforcement officers who respond to a domestic violence call rarely have access to the history and context of violence. When there is evidence of violence by both parties, it is therefore common for both people to be arrested. Some jurisdictions have instituted primary or principle aggressor language to guide officers in situations where both parties have been violent. These guidelines, however, do not eliminate the difficulties of determining the nature of the abuse and the potential risks to each partner. Criminal law is not designed to regulate the dynamics of intimate relationships but to protect citizens from criminal acts. Most actions that distinguish mutual battery, situational couple violence, and intimate terrorism are not criminal offenses and are not visible to responding officers. These actions include isolating a victim from family and friends, controlling personal decisions and movements, using threatening looks, and denigrating value of a partner, among other techniques of coercive control. The presence of violent actions by both parties may lead to legal decisions that categorize a situation as mutual battery when in fact one partner is perpetrating intimate terrorism and the other is responding with defensive violence.

Most jurisdictions now offer diversion of misdemeanor domestic violence offenses to batterer intervention programs. These programs were developed for male offenders, and many concentrate on issues of power and control. Women who are arrested for engaging in situational couple

violence or defensive violence often do not receive appropriate treatment in these groups.

In the civil realm, the presence of domestic violence is one factor that is considered in evaluations of the best interests of children in marital dissolutions. Many states have rebuttable presumption statutes that presume it is not in the best interests of a child to be placed in sole or joint custody with a parent who has perpetrated domestic violence. Claims of mutual battery have become increasingly common in family courts. Judges and family evaluators thus must carefully consider the context of these claims and determine whether violence between parents was truly mutual or was some variation of intimate terrorism, situational couple violence, or violent resistance to abuse. Since nearly half of separating and divorcing couples report abuse in their relationships, determination of the nature and type of abuse and its potential ongoing harm to victims and to children is both complex and essential. The National Council of Juvenile and Family Court Judges, Family Violence Department, sponsors ongoing training and support on evaluating claims of mutual battery in child custody cases.

Continued research on intimate partner violence is needed that attends to the variations that differentiate mutual battery from other forms of violence and abuse in relationships.

NATIONAL CRIME VICTIMIZATION SURVEY (NCVS)

Since the early 1970s, the National Crime Victimization Survey (NCVS) and its predecessor the National Crime Survey (NCS) have provided detailed information about the nature and extent of personal and property victimization in the United States. Much of our current understanding about crime, including but not limited to the extent of reporting to police, how predictors of victimization differ across victim populations, the proportion of crime involving weapons, and the types of injuries sustained in violent crimes comes from analysis of the NCS and NCVS. Throughout its rich history, data and findings from the NCVS have educated the public, guided policy makers, and have informed researchers across a wide variety of disciplines.

The NCVS serves as a model for victimization surveys implemented throughout the world because it incorporates many innovative methodological protocols that enhance its ability to produce reliable estimates of the nature and extent of criminal victimization. These methodological techniques combined with the large sample size and the extensive details collected by the survey on crime events are reasons that many view the NCVS as the most complete and systematic survey of victims in the United States.

This description of the NCVS proceeds in the following fashion. First, an overview of the NCVS is described. Next, details about the complex

methodology of the survey are presented. This includes information regarding eligible sample units, the three basic survey instruments, how crimes are identified, and series victimizations. Finally, this entry concludes with an outline of the advantages and disadvantages of the NCVS.

Brief History

The survey originally named the National Crime Survey was first fielded in 1972. The survey was designed to serve several purposes. First, the NCS served as a benchmark for the Uniform Crime Reporting (UCR) Program collected by the Federal Bureau of Investigation (FBI) statistics on crime reported to police. The NCS gathered data on violent crimes, including rape, robbery, aggravated assault, and simple assault. Data on the nonviolent personal crimes of purse snatching and pocket picking were also collected. And finally, information on property crimes, including motor vehicle theft, burglary, and property theft, was obtained. A second purpose of the survey was to measure the “the dark figure of unreported crime.” That is, crime that does not come to the attention of police. And a third purpose of the NCS was to collect detailed information on characteristics of crime not available in the UCR Program.

The survey functioned well, although it was quickly clear that there was room for improvement. Therefore, beginning in 1979, a thorough redesign of the NCS was started with the purpose of improving the ability of the survey to measure victimization in general, as well as other difficult-to-measure

crimes, such as rape, sexual assault, and domestic violence. The post-redesign survey measured the identical set of crimes but now included data on sexual assault. In addition, the redesigned survey paid more attention to the victim and offender relationship. The redesign was fielded in 1992 using a split sample design. The first full year of NCVS data based on the redesign was available in 1993. It is at this time that the NCS became known as the NCVS.

Methodology

The NCVS is collected using a stratified, multi-stage, cluster sample, with a rotating panel design of households. Because the NCVS sample is composed of addresses, the composition of some of the households changes through relocation, marriage, divorce, death, and/or changes in roommates. Regardless of individual-level changes in household composition, all persons living in the sampled household who are age 12 years or older are interviewed at each of the seven enumerations. A sample household stays in the NCVS sample for 3 years and is interviewed a total of seven times at 6-month intervals. After enumeration 7, a new sample household is rotated into the sample. Based on this design, each household and person in the NCVS is treated independently and is not linked across interviews. As a result, trend analysis must take into account the correlation between enumerations when calculating variances and other statistics.

Survey Instrumentation

The NCVS does not depend on a simple question format to allow the respondent to determine whether he or she were victimized (e.g., “Have you been a victim of a crime?”). Nor does it rely on the field representative’s view as to whether a crime, or what type of crime, was committed. Rather, the NCVS uses a multistage instrument process to determine whether a crime occurred and, if so, what type of crime. This process involves the use of three basic survey instruments: the Control Card (NCVS 500), the Basic Screen Questionnaire (NCVS 1), and the Incident Report (NCVS 2).

Control Card

The Control Card is the basic administrative record for each sample unit. It contains the address

of each sample unit and the basic household data, such as the names of all persons living there, as well as their age, race, sex, marital status, education, and so on. Household income, tenure of the unit, and pertinent information about noninterviews are also included on the Control Card. The Control Card serves as a record of visits, telephone calls, interviews, and noninterview reasons. The Control Card information is updated as needed during each enumeration.

The Basic Screen Questionnaire

The Basic Screen Questionnaire is used to determine—or screen—whether any crimes were committed against the household or against an individual household member during the 6-month reference period. Respondents are prompted to report an incident “even if they do not believe it was a crime.” One example of an NCVS 1 screening question follows:

I’m going to read some examples that will give you an idea of the kinds of crime this study covers.

As I go through them, tell me if any of these happened to you in the last six months, that is since (fill in date).

Was something belonging to YOU stolen, such as

- (a) Things that you carry, like luggage, a wallet, purse, briefcase, book
- (b) Clothing, jewelry, or calculator
- (c) Bicycle or sports equipment
- (d) Things in your home—like a TV, stereo, or tools
- (e) Things outside your home such as a garden hose or lawn furniture
- (f) Things belonging to children in the household
- (g) Things from a vehicle such as a package, groceries, camera, or cassette tapes

OR

- (h) Did anyone ATTEMPT to steal anything belonging to you?

If a respondent answers “yes” to any screener question on the NCVS 1 instrument, an Incident Report (NCVS 2) is completed.

The Incident Report

One incident report is completed for each incident revealed during the screening process. The incident report gathers detailed information on every aspect of the victimization, which includes (but is not limited to) whether there were bystanders, resistance used by the victim, if the victim is insured, time of incident, number of offenders, and location of incident. Although all details of an incident are important, certain incident characteristics are especially significant in the NCVS because they are used to ascertain if, and what type of, crime occurred. These incident details include the following:

- Whether the victim was attacked
- Whether the victim was injured
- The severity of any injuries
- Whether a weapon was present
- Length of any hospital stays
- Whether property was stolen

After the data are collected, they are sent to the Census Bureau (the collector of the data), where a computer program evaluates these specific incident characteristics and determines whether a crime occurred. Furthermore, if a crime occurred, the protocol then classifies the victimization into the appropriate type of crime category. The classification scheme is hierarchical, meaning that an incident is classified into the most serious crime category in which it fits. The crime hierarchy order used in the NCVS is as follows:

- Rape/sexual assault
- Robbery
- Aggravated assault
- Simple assault
- Personal larceny
- Burglary
- Motor vehicle theft
- Property theft

In some instances, a respondent cannot provide the details of each incident. For example, an individual may have been assaulted repeatedly by her spouse

(e.g., about 45 times) during the preceding 6-month reference period. Or a student may be beaten up and harassed by the school bully daily during the reference period. NCVS methodology requires an Incident Report be filled for *each of these events*. However, it is often the case in repeat victimization situations like these that the respondent cannot provide the details of every incident. And without these details, the determination of a crime or the type of crime is impossible. For circumstances like this, a “series victimization protocol” is used. In cases in which there are six or more incidents of a similar nature in which the respondent cannot provide details of each, details of only the most recent incident in the series of incidents is recorded in the Incident Report. This incident is recorded as “series victimization.”

Periodically, additional information on crime-related topics is collected by the NCVS. These supplements are conducted for many different purposes and are often sponsored by other federal agencies. Usually supplements are administered to targeted subsamples of the NCVS sample. Supplements fielded since 1992 include the School Crime Supplement, the Police Public Contact Survey, the Workplace Risk Supplement, and a Stalking Supplement. Data gathered using these supplements are archived as separate data sets at the ICPSR.

Advantages

The NCVS offers many benefits for exploring the extent and characteristics of criminal victimization. One advantage is that the survey is very large. Currently, approximately 43,000 households and 86,000 individuals age 12 years or older are interviewed twice a year. Given this large sample, the survey is characterized by small sampling errors allowing power to make inferences about the population. A second advantage of the survey is that it offers a broad scope of variables associated with criminal victimization, including information about crime victims (e.g., age, gender, race, Hispanic origin, marital status, income, and educational level), criminal offenders (e.g., gender, race, approximate age, drug/alcohol use, and victim–offender relationship), and the characteristics of the crime (e.g., time and place of occurrence, use of weapons, nature of injury, and economic consequences). Third, the survey has a history of high response rates. In general,

household response rates have varied between 90% and 96% of eligible households and between 89% and 92% of eligible individuals. And finally, an advantage of the NCVS is that it provides information on victimization that was both reported and not reported to the police. Research demonstrates that many crimes are not reported to the police, and reporting rates differ across crime type and victimization characteristics. The NCVS asks respondents about crimes they experienced and whether the crimes were or were not reported to the police.

Disadvantages

Like all data, the NCVS has some limitations. First because the survey is designed to generate *national* estimates of victimization, it cannot be used to inform about cities, counties, or states. One can disaggregate to the region level (e.g., Northeast, South, Midwest, and West), although this level of aggregation has limited value. A second limitation is that the survey does not collect information on persons age 11 years and younger. Third, because one must live in a housing unit or group quarter to be eligible for this survey, homeless persons, prisoners, or other institutionalized individuals; members of the armed forces living in military barracks; and crews of vessels are excluded from the NCVS sample. And finally, the NCVS collects data on a limited assortment of crime (noted above). This coverage excludes crimes such as white collar crime, crimes against businesses, arson, and kidnapping. Related, because the methodology requires speaking directly to the victim of the crime, the NCVS does not offer information on homicide.

NATIONAL CRIME VICTIMIZATION SURVEY, SUPPLEMENTS

Throughout its more than 35-year history, and especially since it was redesigned in 1992, the National Crime Victimization Survey (NCVS) has provided a platform for additional studies related to various aspects of crime. These studies, commonly called supplements, are of three types: those that fill informational gaps about offenses not measured in the NCVS, those sponsored by federal agencies to meet legislative mandates or programmatic informational needs, and those conducted to inform on topics related to crime and safety. They have covered a variety of subjects and have provided a relatively economical approach for obtaining information about crime, public perceptions of safety, and the criminal justice system not provided by the ongoing NCVS.

Supplements to the NCVS have been initiated in several ways. In some instances, such as the Workplace Risk Supplement (WRS), a federal agency contacted the Bureau of Justice Statistics (BJS) about conducting the survey. In other cases, BJS has identified a perceived informational need and either fielded the study itself or worked with other agencies to do so.

NCVS supplements have always been administered after the regular interview with each respondent and have been conducted as independent studies rather than as extensions of the NCVS. Only one, the WRS, used information collected during the regular NCVS interview (other than respondent age) to screen in respondents to the supplement. The WRS was administered to persons age 16 years and older who said during the NCVS interview that they were employed. A fundamental reason supplements to the NCVS have not made use of information collected during the regular interview is that until 2006, the NCVS was primarily a paper and pencil survey, which is a mode of interview that does not facilitate incorporating information into a supplemental data collection. Because the survey is now conducted using computer-assisted interviewing, it would be feasible for

future supplements to build on the information collected during the regular NCVS interviews to examine issues in more depth or expand the scope of the ongoing survey.

Supplements provide many advantages to staging completely separate data collections. It is far less expensive to add a battery of questions to an ongoing survey than to field a completely new data collection. The NCVS sample is large and therefore provides a robust platform for conducting additional studies. Data from most supplements can be linked to data on victimization from the NCVS, enabling, for example, how victimization experience may be related to the supplement's subject area. The primary disadvantage to conducting supplements is that they increase the burden on respondents and may inhibit future participation in the ongoing survey. NCVS supplements have historically resulted in somewhat higher rates of noninterview than the regular NCVS, as some respondents who participated in the NCVS interview decline to be interviewed for the supplement. With the exception of the Victim Risk Supplement, all supplements to the NCVS have been conducted during 6-month periods to use the full NCVS sample.

NCVS supplements have covered a broad range of topics. Some have been conducted repeatedly. The School Crime Supplement has been conducted biannually since 1995, and the Police-Public Contact Survey has been conducted four times since 1996. As with the ongoing NCVS, the data sets for supplements are archived at the National Criminal Justice Archive and Information Network once initial estimates have been released by the sponsoring agency to enable secondary analysis of the data.

Supplements

National Survey of Crime Severity (NSCS) (1977) was the largest survey ever conducted to assess how the public ranks the severity of a wide range of offenses. Each of the 60,000 respondents was asked to rank a subset of 25 of a total of 204 specific descriptions of criminal events. The ratings were combined, and overall severity scores were produced for all 204 events. The highest score was for "A person plants a bomb in a public building. The bomb explodes and 20 people are killed." The lowest score was for "A person under 16 years old plays hooky from school."

Victim Risk Supplement (VRS) (1984) was conducted in February 1984 and collected information about perceptions of the safety and crime measures people take to prevent crime at home and at the workplace.

School Crime Supplement (SCS) (1989, 1995, biannually since 1999) is a periodic supplement funded by the National Center for Education Statistics to obtain information related to crime and safety in our nation's schools. Respondents are juveniles 12 to 18 years of age who attended a public or private school during the 6 months prior to the interview. The SCS asks students about their experiences with, and perceptions of, crime and violence that occur at school, about the presence of weapons and drugs at school, about preventive measures schools and students take concerning crime, and about their attitudes related to fear of victimization.

Police-Public Contact Survey (PPCS) (1996, 1999, 2002, 2005, 2008) is a periodic supplement conducted to address the mandate established by the Violent Crime Control Act of 1994 to collect, evaluate, and publish data on the use of excessive force by law enforcement. The supplement collects data on the extent and nature of public contacts with the police and includes questions about police-initiated use of force and stops for routine traffic violations.

Workplace Risk Supplement (WRS) (2004) was funded by the National Institute for Occupational Safety and Health to provide data to improve workplace violence prevention efforts. It included questions that replicated those on the 1983 VRS but with a focus on the workplace environment. It also included questions related to employee knowledge of workplace violence prevention policies, practices and training, as well as security measures in place in the workplace.

Special Victimization Study (SVS) (2006) was conducted with funding from the Office on Violence Against Women to provide comprehensive estimates of the prevalence, characteristics, and consequences of stalking in the United States. The supplement was administered to all persons age 18 years and older in the NCVS sample.

Identity Theft Survey (ITS) (2008) was a collaborative effort of agencies within the Department of Justice's Office of Justice Programs and the Federal Trade Commission. The ITS is built on

previous BJS and FTC efforts to measure the prevalence and characteristics of identity theft, and it is the largest fielded survey of this offense that has been conducted.

NATIONAL INCIDENT-BASED REPORTING SYSTEM (NIBRS)

The National Incident-Based Reporting System (NIBRS) is the new format used by the Federal Bureau of Investigation (FBI) to collect crime data from law enforcement agencies as part of its Uniform Crime Reporting (UCR) Program. NIBRS is replacing the previous format for reporting UCR Program data known as “the summary reporting system.” For the summary reporting system, law enforcement agencies submitted aggregate crime counts. In contrast, NIBRS collects crime information at the incident level. This change results in data that can provide insights into victimization reported to the police in a way previously not possible. As such, NIBRS data are useful to researchers and policy makers concerned with criminal victimization.

Origins

Although the FBI has collected aggregate crime data from law enforcement agencies since the 1930s, changes in technology and criminology necessitated more sophisticated information. Specifically, recent improvements in technology enabled the collection of more detailed crime information, and modern developments in the understanding and explanation of criminal offending and victimization generated a demand for such data. In response to demands for improved police data, the Bureau of Justice Statistics (BJS) and the FBI commissioned a team to reevaluate the UCR Program. This study resulted in the *Blueprint for the Future of the Uniform Crime Reporting Program* or *The Blueprint*. *The Blueprint* described an incident-based crime collection system that would eventually become today’s NIBRS. After several years of piloting and finalizing this new system, South Carolina became the first state to submit its crime data to the FBI in NIBRS format in 1991.

Information Collected

NIBRS encompasses several substantial changes for UCR Program data as compared with the summary reporting system. NIBRS covers a wider variety of offenses than the 8 Index offenses captured by the summary reporting system. These 8 Index offenses included murder and non-negligent manslaughter, forcible rape, robbery, aggravated assault, burglary, larceny theft, motor vehicle theft, and arson. NIBRS collects incident-level details for 46 Group A offenses, which include the former 8 Index offenses. Examples of these additional crimes range from kidnapping and forcible sex offenses beyond rape (such as sodomy and sexual assault with an object) to vandalism, gambling offenses, and fraud offenses. NIBRS also compiles a count of 11 Group B offenses. Although Group A offenses are those known to police, Group B offenses are only counted if an arrest is made. Group B offenses are comparable with the Part II offenses in the summary reporting system and include crimes such as disorderly conduct, driving under the influence, and curfew violations.

In addition to expanding the number of crimes reported to the UCR Program, NIBRS captures general characteristics not included in the summary reporting system. NIBRS distinguishes

between attempted and completed crimes. NIBRS also adds the category of “crimes against society” to the existing classifications of crimes against persons. This new classification allows the collection of vice crimes like prostitution, gambling offenses, and drug offenses, which are often referred to as so-called victimless crimes. For each criminal incident, NIBRS collects information on up to 10 offenses. This information eliminates the need for NIBRS to continue the Hierarchy Rule of the summary reporting system, which only counts the most serious crime in a multi-offense incident.

The main difference between NIBRS and the summary reporting system, however, is the collection of incident-level data. For the Group A offenses, NIBRS collects detailed information within six segment levels: administrative, offense, property, victim, offender, and arrestee. Overall NIBRS can collect up to 53 distinct data elements to describe each criminal incident. Thirteen of these elements are required for all criminal incidents. Examples of these characteristics include incident date, location of the incident, and type of victim. Thirty-six of the other data elements are mandatory but only if they are relevant to a particular crime. For example, a weapon must be reported for a personal crime like murder but not for a property crime like theft. Up to 13 data elements can be used to describe individual victims. Depending on the crime, these elements include victim demographics, injury, victim–offender relationship, and circumstance codes for aggravated assaults and homicides. NIBRS can collect data for up to 999 victims per criminal incident; however, most incidents involve one or two victims.

The summary reporting system does allow for incident-level details as part of its Supplementary Homicide Report (SHR), but the SHR is much more limited than NIBRS. The SHR only collects incident details for homicides. The SHR also collects fewer incident details than NIBRS. Finally, the SHR, like the rest of the summary reporting system, does not provide any unique incident identifiers. This omission restricts the SHR’s ability to update data to include, for example, subsequent clearance information.

Using NIBRS Data to Study Victimization

NIBRS data only recently have been used by criminologists and other researchers to study crime

issues. This limitation is partly because these data have been publicly available to researchers since 2000. NIBRS data are generating increased attention and interest because these data are collected at the incident level and permit the study of criminal victimization. Currently, researchers have most commonly used the data to study victims of violent crimes such as homicide, rape, and assault. Within this scholarship, particular consideration has been given to child victims as well as to elderly victims. Issues concerning intimate partner violence have been given attention using NIBRS data. Incident-level details have yielded new insights regarding patterns of intimate partner violence for opposite-sex couples as well as for same-sex couples. Victims of offenses like hate crimes also have been studied using NIBRS data. In addition to focusing on particular types of victims and patterns of victimization, researchers have investigated the efficacy of victim-oriented policies. For example, researchers have used NIBRS data to examine the effectiveness of mandatory arrest policies on domestic violence incidents in different cities. Current studies only have begun to explore the ability of NIBRS data to inform victimization issues.

Limitations

NIBRS data have several benefits, especially over the traditional summary reporting system, with regard to the study of victimization. These data, however, also have certain limitations that restrict their utility. One limitation stems from the fact that NIBRS data derive from official police records. As such, like any crime data generated from police records, the data exclude nonvictims and victims who do not report crimes to the police. Other sources such as the National Crime Victimization Survey (NCVS) do provide information on nonvictims for comparisons. Researchers such as Lynn A. Addington and Callie Marie Rennison have attempted to use NIBRS and NCVS data in a complementary way to address this limitation.

Another current limitation with NIBRS data is that it lacks nationwide coverage, and those law enforcement agencies that do participate are not a nationally representative sample. As with the summary reporting system, participation in the UCR Program remains voluntary under NIBRS. Unlike the summary reporting system, law enforcement

agencies must be certified before they are eligible to submit data in NIBRS format. The certification process is complex and can take years to complete successfully. As a result, the conversion process has been gradual. As of 2007, 30 states are NIBRS-certified and NIBRS agencies cover 25% of the U.S. population according to information collected by the Justice Research and Statistics Association. The states and law enforcement agencies that have implemented NIBRS do not constitute a representative sample of U.S. law enforcement agencies or states. Within the 30 NIBRS-certified states, not all agencies submit data in NIBRS format. Only 10 of these states are 100% NIBRS-reporting; the others report in varying levels of less than full participation. In general, law enforcement agencies that participate in NIBRS tend to represent smaller population areas. As of 2007, no agency covering a population of more than 1 million participated in NIBRS. As a result, victimization research that uses NIBRS data is limited in its wider generalizability, especially with regard to the largest jurisdictions.

NATIONAL VICTIMIZATION AGAINST COLLEGE WOMEN SURVEYS

A countless number of studies have reported consistently that college women are a high-risk group for sexual victimization, especially at the hand of an acquaintance or date. Most of these studies have been executed at a single campus with a convenience sample of students. The Bureau of Justice Statistics published two special reports in 2003 and 2005 on the violent victimization of college students using data from the National Crime Victimization Survey (NCVS). Noteworthy is that the NCVS sample is not a national representative sample of college students generally or college women specifically. The National Violence Against Women Survey (NVAWS) is characterized by the same sampling limitation.

To date, only four studies have used a nationally representative sample of college women to examine the extent and nature of their victimization. This entry describes each of these four studies and highlights their methodology and major findings.

The National Survey of Inter-Gender Relationships

In the early 1980s, the National Institutes of Health, with administrative assistance from the Ms. Foundation, funded the National Survey of Inter-Gender Relationships; Mary Koss was the principal investigator. The study was conducted during the 1984–1985 academic year and involved a post-master's level psychologist administering a self-report questionnaire in classroom settings. The psychologist administered the survey to 6,159 women and men enrolled in 32 private, public, or

religious 2- and 4-year post-secondary institutions with 1,000 or more enrolled students. Military and graduate schools with no undergraduate affiliation were excluded. The survey included more than 300 questions about such topics as sexual experiences and their characteristics as well as demographic information. The response rate was 98.5%.

Sexual aggression and victimization data were collected using the 10-item Sexual Experiences Survey (SES). Responses to the SES items were used to estimate women's reports of experiences and men's reports of perpetrating rape, attempted rape, sexual coercion, and sexual contact, including the prevalence rates since the age of 14 years and of incidence during the previous year.

The results revealed that since the age of 14, more than half of the college women (53.7%) reported some form of sexual victimization. Furthermore, 15.4% of women had been raped, 12.1% had experienced attempted rape, 11.9% were sexually coerced, and 11.4% had experienced sexual contact. Their results also showed that the rape estimates from the two official sources of victimization rates, Uniform Crime Reporting (UCR) Program and the National Crime Survey (NCS), underestimated the extent of rape. The work highlighted the "hidden" nature of sexual victimization, in part, because the results showed that the offender was someone known to the victim, and thus, the incident went unreported to law enforcement.

This study was the first national study to estimate the extent of sexual victimization among college women. It also advanced the measurement of sexual victimization with its use of the SES items that used behaviorally specific language to describe sexual acts. Even today, the 1987 publication of the article by Koss, Gidycz, and Wisniewski reporting the prevalence estimates from the SES is among the most cited articles in the field of college women's sexual victimization. Given its established validity and high reliability, the SES also is among the most widely used instruments to measure the scope of sexual victimization experiences. In 2007, Koss and her colleagues revised the SES.

The National College Women Sexual Victimization Study

Almost a decade went by before the next national study of the sexual victimization of college women

was completed. Funded in the mid-1990s by the National Institute of Justice, Bonnie Fisher and Francis Cullen built from the work of Mary Koss, Dean Kilpatrick, Pat Tjaden, and Nancy Thoennes to design the National College Women Sexual Victimization (NCWSV) study. The goals were to update and advance the current state of knowledge about the extent and nature of sexual victimization of college women.

The NCWSV study was a computer-aided telephone survey of a randomly selected, national sample of 4,446 women who were enrolled in 233 2- or 4-year post-secondary institutions during the fall of 1996. The sample was limited to schools with at least 1,000 students. Trained female interviewers employed by Abt Schulman, Ronca, and Bucuvalas Inc. (Abt SRBI, New York, NY) administered the survey via computer-aided telephone interviews between late February and early May 1997. The response rate was 85.6%.

Similar to the NCVS, the NCWSV used a two-stage measurement process that included behaviorally specific screen questions followed by a detailed incident report. If a respondent answered "yes" to any of the screen questions, she was then asked how many times the act was experienced since school began in the fall of 1996. For each number of times, the interviewer completed an incident report. This report asked questions about the nature of the events, including its location and things that occurred prior to (e.g., drinking alcohol), during (types and degree of sexual contact, self-protective action), and after the incident (injury, reporting to the police). The survey also asked questions about respondents' demographic characteristics, lifestyles or routine activities, living arrangements, and prior sexual victimizations. The NCWSV measured the incidence of types of completed and attempted sexual victimization that included rape, sexual coercion, and unwanted sexual contact with and without force or threat of force. Also measured were stalking and visual (e.g., someone exposed their sexual organs to them) and verbal (e.g., sexist remarks and cat calls) sexual victimization.

The major findings revealed that across rape, sexual coercion, and unwanted sexual contact, 15.5% of college women had experienced at least one victimization incident. During the 6- to 7-month reference period, close to 3% of college

women were raped. Slightly more than 13% of women indicated that they had been stalked during this time, with an average stalking lasting 60 days. Most students experienced verbal sexual victimization. Visual sexual victimization was less common. Supportive of Koss's pioneering work, most victims know the person who sexually assaulted them, with several victimizations happening while on a date. College women were victimized both on and off campus, with off-campus locations being more common. Most victimizations were not reported to law enforcement; however, most victims told a friend about their incident. Supportive of past research, risk factors across the various types of sexual victimization included (1) frequently drinking enough alcohol to get drunk; (2) being unmarried; (3) having been a victim of prior sexual assault before the current school year began; and (4) for on-campus victimization, living on campus.

Among the NCWSV's contributions to the college women victimization field includes being the first national study of the stalking of college women. Also, its two-stage methodology showed that the NCVS methodology could be adapted to a college population. The NCWSV also affirmed that the sexual victimization of college women was a growing national issue in need of prevention and intervention strategies. The NCWSV data have been used in several other published works by Fisher and her colleagues to examine reporting behavior, the effectiveness of self-protective behaviors, and recurring victimization.

The National College Women Violent Victimization Study

Funded by the Bureau of Justice Statistics, Bonnie Fisher and Francis Cullen designed The National College Women Violent Victimization (NCWVV) study to explore the extent to which female college students experience specific types of violence (e.g., rape, sexual assault, unwanted sexual contact, robbery, and simple and aggravated assault) and nonviolence more broadly defined (e.g., verbally harassed, larceny, vandalism, and burglary) since school began in the fall of 1996. To arrive at these victimization estimates, the NCWVV study employed the two-stage measurement methodology (victimization screen questions with follow-up

incident report) used by the NCVS redesign Phase III and NCWSV study. Questions on the NCVS main survey and incident report were revised for use with a college women sample.

The NCWVV employed the same criteria for sample inclusion, sampling design, and survey administration as the NCWSV study. A total of 4,432 female students enrolled at 233 two- and four-year post-secondary institutions participated in the study. The field period lasted from the end of March to mid-May 1998. The response rate was 90.7%.

The data revealed several interesting findings. Most victimization experienced by female students is nonviolent. Although one quarter of the college women experienced a nonviolent victimization, the percentage of the sample experiencing a violent victimization was about 7%. The most common violent crime experienced by college women is simple assault. Consistent with the NCWSV results, most violent victimizations occur among people who know one another, in private settings (living areas), and in the evening or late night hours, and they are perpetrated by single offenders who are using alcohol or drugs. Most violent victimizations, especially sexually related assaults, are not reported to police officials. Adding to the well-established debates about the measurement of sexual victimization, especially Koss's accusation about the limitations of the NCVS, the NCWVV study showed that estimates of rape/sexual assault victimization using the NCVS are lower than estimates derived from studies using alternative ways of measuring this type of victimization.

A National Study of Drug-Facilitated, Incapacitated, and Forcible Rape

Funded by the National Institute of Justice, Dean Kilpatrick and his research team identified how many women had ever been raped or sexually assaulted during their lifetime and within the last year. For comparison purposes, the study had two samples: (1) a national telephone household sample of 3,001 women and (2) a college sample of 2,000 women who were attending 253 different 4-year post-secondary institutions. Abt SRBI employed female interviewers who used computer-aided telephone interviewing to administer the surveys between late January and late June 2006. The survey asked women questions about five

areas: (1) demographic information, (2) opinions about reporting rape to police and disclosure to others, (3) questions about different forms of rape, (4) questions about the rape experience (e.g., victim–offender relationship and medical care), and (5) questions about women’s mental health histories (e.g., posttraumatic stress disorder, major depression, alcohol use and abuse, and drug use and abuse). They measured three forms of rape: (1) drug and alcohol-facilitated rape in which the perpetrator deliberately gives a victim substances without her permission or tries to get her drunk and the victim is passed out or awake but too drunk to consent to sexual contact; (2) incapacitated rape in which the victim voluntarily uses drugs or alcohol and is passed out or awake but too drunk to consent to sexual contact; and (3) forcible rape in which the victim experiences force, threat of force, or sustains injury during the assault.

Key findings from Kilpatrick’s study revealed that college women had a much higher prevalence of rape in the past year than women in the general population. Slightly more than 5% of college women were raped in the past year compared with nearly 1% of women in the general population. Drug and alcohol-facilitated rape (DAFR) and incapacitated rape (IR) were more prevalent than forcible rape. DAFR and IR were nine times more prevalent among college women than among the general population of women. Classmates, friends, and boyfriends were the offenders in most forcible rapes, and friends, classmates, and strangers were the offender in the most DAFRs/IRs. Victims of DAFR/IR were less likely to report to law enforcement than were victims of forcible rape.

Conclusion

Separately and collectively these four national studies of the sexual victimization of college women have contributed to our understanding of the extent and nature of the victimization of college women. Each collected a unique, yet rich, data set that has been used in numerous publications that are well cited among researchers, policy makers, and practitioners who are interested in not only the extent and nature of the victimization of college women but also in developing effective prevention and interventions.

NATIONAL VIOLENCE AGAINST WOMEN SURVEY (NVAWS)

The National Violence Against Women Survey (NVAWS) is a telephone survey that was conducted by the Center for Policy Research with funding from the National Institute of Justice and the Centers for Disease Control and Prevention. The goal of the survey was to increase understanding of violence perpetrated against women in the United States. To provide a context for this understanding, the survey sampled both women and men. Thus, the survey provides comparable

data on the experiences of women and men as victims of violence.

Survey Methods

The NVAWS consists of telephone interviews with 8,000 U.S. women and 8,000 U.S. men 18 years of age and older. The survey includes both Spanish-speaking and English-speaking respondents. The sample was drawn by random-digit dialing of households with landline telephones in the 50 states and the District of Columbia. Interviews were conducted from November 1995 to May 1996 using a computer-assisted telephone interviewing system.

Respondents to the survey were queried about their general fear of violence and their ways of coping with that fear; psychological and emotional abuse they experienced by current and former spouses and cohabiting partners (same-sex and opposite-sex); physical assaults they experienced as children by adult caretakers; and rape, physical assault, and stalking they experienced over their lifetime at the hands of all types of perpetrators. Respondents disclosing victimization were asked detailed follow-up questions about their relationship to the perpetrator; the frequency and duration of the violence; situational factors surrounding their victimization; the extent and nature of injuries sustained; their utilization of medical and mental health services; their involvement with the justice system; and the amount of time they lost from routine activities, such as work, school, and household chores.

To protect the confidentiality of the information being collected, interviewers were required to sign a confidentiality agreement specifying that they would not share any information generated from the survey with persons outside the research team. In addition, only a ten-digit telephone number was used to link the respondent to the interviewer. Once the survey was completed, the last four digits of the telephone number were deleted from the database.

Protocols were established to minimize the potential for inflicting additional trauma on victims. Before fielding the survey, interviewers were given extensive training on the content of the survey, the effects of violent victimization, and appropriate

ways to respond to disclosures of victimization. Respondents who showed stress during the interview were given telephone numbers of rape and/or domestic violence crisis centers in their area.

To minimize the potential for placing victims in jeopardy of continued violence, during initial contact with household members, the survey was introduced as a survey on "personal safety" rather than on violent victimization. In addition, respondents were given the opportunity to call back and finish their interview at a time when no one else in their household could overhear their responses.

Major Findings

Rape

The NVAWS found that 18% of surveyed women and 3% of surveyed men were raped at some time in their lives, whereas 0.3% of surveyed women and 0.1% of surveyed men were raped in the 12 months preceding the survey. Among victims raped in the previous 12 months, women averaged 2.9 rapes and men averaged 1.2 rapes.

Nearly all of the female rape victims (99.6%) and 85% of the male rape victims were raped by a male. Overall, women tended to be raped by a current or former intimate partner, whereas men tended to be raped by an acquaintance.

Among victims raped as adults (since their 18th birthday), 32% of the women and 16% of the men sustained some type of physical injury. Of the women injured, 36% received medical treatment for their injuries. Only 19% of the women and 13% of the men who were raped since their 18th birthday said their rape was reported to the police.

Stalking

Using a definition of stalking that required victims to feel a high level of fear, the NVAWS found that 8% of surveyed women and 2% of surveyed men were stalked at some time in their lifetime, whereas 1% of surveyed women and 0.4% of surveyed men were stalked in the 12 months preceding the survey. Overall, 78% of the stalking victims identified by the survey were women, and 87% of

the stalkers were men. Among all stalking victims, 77% of the women and 64% of the men knew their stalker. Despite the high level of fear required, less than half of the victims were directly threatened by their stalker.

About half of all stalking victims said their stalking was reported to the police. In addition, 28% of the female victims and 10% of the male victims obtained a protective/restraining order against their stalker.

Intimate Partner Violence

The NVAWS found that 22% of surveyed women and 7% of surveyed men were physically assaulted by a current or former intimate partner at some time in their lifetime, whereas 1.3% of surveyed women and 0.9% of surveyed men were physically assaulted by a current or former intimate partner in the 12 months preceding the survey. Overall, female victims experienced more chronic and injurious physical assaults by intimate partners: Female victims averaged 6.9 physical assaults by the same partner, whereas male victims averaged 4.4 assaults. Female victims were twice as likely as male victims to be injured (42% vs. 20%). About a quarter of female victims reported their victimization to the police, compared with 14% of male victims.

NEIGHBORHOOD WATCH PROGRAMS

Neighborhood Watches are grass-roots, community-based, crime-reduction organizations, normally operated in partnership with the police and sometimes also including collaboration with local authorities. The terms *Block Watch* and *Home Watch* are sometimes used as alternatives to Neighborhood Watch. Activities associated with Neighborhood Watch typically include meetings of members, erection of street signs indicating that Neighborhood Watch operates in the area, decals on the windows of individual members, and more or less regular liaison with local police. Other activities can range from property marking to street patrol to improvements in security. The main purposes of Neighborhood Watch are to provide protection to members, in particular from residential burglary, although other crimes may be of concern also, to reduce fear of crime, and to improve the supply of intelligence to the police in order that they can better detect crime.

History

Community involvement in crime prevention has a long history. Citizen collaboration with and participation in policing activities likewise has a long history. Both go back before the dawn of professional policing. In this sense, formal Neighborhood Watch programs describe efforts to reengage and regularize community members in crime control. The first Neighborhood Watch programs were operated in the United States in the early 1970s and seemed to bring promising results. Since that time, Neighborhood Watch programs have expanded rapidly and are now widely found, especially in the English-speaking world. The first was set up in the United Kingdom in 1982 and in Australia in 1983.

Theoretical Basis

Neighborhood Watch has high face validity in regard to its various purposes. As a vehicle for improving crime detection and prevention,

- Neighborhood Watch recognizes that the police are poorly placed either to detect or to prevent crime on their own. Community cooperation and collaboration are needed.
- Crime detection generally turns, at least in part, on the supply of information from members of the public, and conviction often depends on the willingness of citizens to provide evidence in court. One of the main planks of Neighborhood Watch is that members act as the “eyes and ears” of the police, reporting suspicious activities so that the police can take action.
- The improvements in detection that may be expected to result from Neighborhood Watch might then help prevent crime through the incapacitation or deterrence of the offenders caught and convicted.
- Crime might also be prevented by the perceived increases in risk to offenders who are made aware of the operation of the program through the signs and stickers alerting them to its presence in certain areas. The offenders are alerted to the relatively high level of vigilance of residents and decide that they will not commit the crimes they would otherwise engage in.
- The property marking and security improvements that are often encouraged through Neighborhood Watch reduce the opportunity for crime and members are thereby expected to benefit from reduced risks.
- Enhanced community functioning as members come to know and trust one another is expected both to facilitate mutual guardianship and hence risks of crime and to provide for better opportunities for informal social control as residents come to recognize and be recognized by potential miscreants who will thereby be inhibited from criminal activity.

As a vehicle for reducing fear of crime and increasing public confidence in the police,

- Neighborhood Watch provides a vehicle through which concerned members of the public can exert control and feel they are exerting control over their local conditions. Members are therefore less dependent on the police and less vulnerable to predatory offenders in relation to whom they would otherwise feel more at risk and more helpless to do anything.

- Neighborhood Watch provides a vehicle through which the police can communicate with the public, to convey to them reassuring messages when these are needed, and to correct misapprehensions about levels of crime and crime risk.
- Neighborhood Watch provides a mechanism through which the police can gauge community concerns and priorities, in order that they can deliver services that are attuned to reducing sources of anxiety about crime and disorder.

Research Findings

Presumably because of its high face validity, Neighborhood Watch has enjoyed widespread public support. Schemes promise to provide access to the police and protection from crime while demanding little from participants. Most citizens seem, in principle, to be happy to cooperate with the police in setting up Neighborhood Watches to help to protect their community. They do so either out of enlightened self-interest or out of a sense of social responsibility. According to the British Crime Survey (BCS) in England and Wales by 1992, only 10 years after the establishment of the first scheme, 22% of all households belonged and 30% of all households were covered. This rose to 27% members covering 38% of the population by 2000. It has been estimated that there were 42,000 schemes in 1988, 130,000 in 1996, and 155,000 in 2000. By any standards, this comprised a large-scale, rapidly expanding voluntary movement. Since 2000, however, membership has declined. In 2006–2007, the BCS found that it had dropped to 16% of all households, although respondents indicated that 32% still lived in areas covered by schemes.

Quite substantial variations have been found in the ways in which Neighborhood Watch has been implemented within and across jurisdictions. The size of schemes has varied from around 20 houses to as many as 3,000 or more. Different schemes have included differing types of provision, for example, social events, formal problem-solving meetings, newsletters, and property marking services, in addition to street signs and decals in the windows of individual households. Funding and administration has sometimes been the responsibility of local residents, sometimes the police, and sometimes partnerships.

Neighborhood Watch has been most easily established in stable, better off, lower crime neighborhoods where there are already relatively strong social institutions. It is less easily established in fragmented, fractured communities with transient populations and relatively high levels of crime. Neighborhood Watch membership has been found to be disproportionately high among those who are in general terms more advantaged and more settled. For example, in England and Wales in 2006–2007, 28% of “wealthy achievers” were members of schemes, but only 7% of the “hard pressed” belonged. Likewise membership was higher where the “household reference person” (HRP) was older than younger (for example, 24% among 60-year-olds and older, but 5% among 16- to 24-year-olds). It was twice as high where the HRP was White (17%) rather than a member of an ethnic minority group (8%). It was also twice as high among owner occupiers (19%) as compared with social renters (9%). It was three times as high for those who had lived in the neighborhood for more than 10 years (22%) than for those who had been there for less than 2 (7%). It was more than twice as high among the married (19%) as against the single (8%). Among the economically active, it was seven times as high among the employed (14%) compared with the unemployed (2%).

With regard to crime, disorder, and security, membership of Neighborhood Watch schemes was more than twice as likely among those living in areas of low physical disorder (17%) than those living where the level of physical disorder was high (8%), and among those with high levels of home security (20%) as compared with those with relatively little (10%) or no home security (7%). Members suffered lower rates of crime than non-members (for example, 4% compared with 8% for vehicle-related theft and 2% compared with 3% for burglary).

Although Neighborhood Watch schemes have been established easily in many neighborhoods, it has been more difficult to sustain enthusiasm. A local crime event might stimulate interest, but if few additional incidents follow, interest seems characteristically to dwindle and many schemes become moribund unless they have an especially committed co-coordinator. What mostly remain are signs in the street that Neighborhood Watch is

in operation and decals in the windows of the homes of those who originally joined. In some areas, in part in response to this dwindling, the police have developed automated systems for feeding information to co-coordinators to cascade down to members with a view to maintaining enthusiasm and the benefits deemed to lie in having a vigilant citizenry who will report suspicious behavior to the police. Such arrangements have included automated phone messages and, more recently, emails and Web links. These developments have been put in place also in part because of the servicing demands that Neighborhood Watch can put on the police. To maintain enthusiasm within Neighborhood Watch schemes, police participation as partners is needed. In many small Neighborhood Watch areas, the levels of crime do not warrant the allocation of police resources, although members of the public belonging to Neighborhood Watch expect that their schemes will be actively serviced by the police. The police have therefore devised relatively low-cost methods of managing them. They have standardized what they offer and require that groups indicate that there is real demand and commitment before they agree to the establishment of new schemes.

Although there is anecdotal evidence that schemes have been associated with crime drops, the little strongly designed systematic research that has been undertaken has not generally been able to detect significant or consistent benefits from Neighborhood Watch in terms of crime detection or prevention outcomes. Falls in crime have not been observed, and reports of useful information to the police do not seem to have been increased. Neighborhood Watch may also do as much to reinforce anxieties among the safe but scared as to reassure them. Research findings on this do not find any consistent effects patterns.

This is not to say that Neighborhood Watch never has or never can be effective in reducing crime. In the Kirkholt Burglary Reduction Project (which operated in a White working-class housing estate in Rochdale in northeast England), small schemes (termed *Cocoon Neighborhood Watches*) were set up around those who had suffered burglaries. The cocoons comprised just half a dozen properties surrounding the one that had been burgled. These cocoons were designed to reduce

the levels of repeat victimization that had been found to be high on the estate. Alongside a package of other measures (including security upgrades and the removal of cash prepayment meters for electricity and gas, which had been preferred targets of burglars), the introduction of the cocoons was associated with a substantial reduction in levels of burglary, from 25 per 100 to 6 per 100 dwellings during a 3-year period. It is unclear what role the cocoons played in producing the falls in numbers of burglary incidents. The fact that risks for repeats are found to be most elevated in the short term after an incident, and the more recent research suggesting that nearby properties are also at increased risk in the aftermath of an incident, suggests that the cocoon watches may have made a contribution even if vigilance faded and interest atrophied as has been widely found elsewhere to be the typical pattern.

Legacy

Watch schemes have been popular, and an almost innumerable variety of look-alikes have taken hold since the original Neighborhood Watches were set up. Think of almost any category of potential victims, and somewhere a watch scheme can be found to cater for it. So, for example, there is Airport Watch, Allotment Watch, Beach Watch, Boat Watch, Business Watch, Campus Watch, Caravan Watch, Church Watch, Farm Watch, Fish Watch, Forecourt Watch, Game Keeper Watch, Golf Watch, Lorry Watch, Park Watch, Pub Watch, Racing Stable Watch, School Watch, Shop Watch, Street Watch, Taxi Watch, Vehicle Watch, Wildlife Watch, and Zoo Watch. As with Neighborhood Watch, these reflect the face validity of watching. It may be that where crime levels are relatively high, for example, among retailers and bars, targeted cooperative watch schemes (as with Kirkholt's cocoon watches) provide the basis for collective crime prevention efforts that are more promising than those in neighborhoods with low crime levels and little continuing incentive to play an active part.

Assessment

Some of the early anxieties about Neighborhood Watch have not turned out to be well founded.

The vigilantism that some were concerned about does not seem to have materialized. There have been few reports of nosy, prying, malicious, curtain-twitching neighbors. Levels of intolerance toward those who choose to live legal, but otherwise atypical lifestyles do not seem to have increased significantly. Just as Neighborhood Watch has disappointed many for its apparent inability to bring about the preventive benefits hoped for, it has also lacked the power to bring about the unwanted negative effects that some also feared. That said, there have, though, been suggestions from research on both sides of the Atlantic that young Black men may be treated as threats and in being treated as threats become threats because they are not accepted or included within the communities in which they reside. This implies that that aspect of Neighborhood Watch that is concerned with surveillance and the mobilization of formal social controls may be in some tension with that aspect which stresses the creation of social cohesion involving all local residents such that mutual concern and informal social control is fostered.

The police response to the heavy demands made on them to support Neighborhood Watch has led unsurprisingly to efforts to streamline the administration, develop standard procedures, and acquiesce to requests to set up Neighborhood Watches only when there is significant resident interest and support. Although this may be sensible for Neighborhood Watches in low-crime neighborhoods, as a way of reducing the risk that resources might otherwise be diverted to the less needy at the expense of those that are more in need, for high-crime neighborhoods something else is called for. Here, if community engagement has a role to play in reducing crime, improving detection, and reassuring the public, more active and resource-intensive strategies may be required.

In high-crime neighborhoods with a rapid turnover of residents, where the stronger tend to be those that leave, where there are high levels of intimidation, where households comprising complete families are scarce, where the physical fabric is often poor, where levels of disorder are high, where a significant subsection of the population is involved in crime, where authorities are treated with suspicion, where levels of mutual trust are low, where morale is low, and where legitimate opportunities are in short supply, the kind of

community participation called for in Neighborhood Watch can only plausibly be achieved with a great deal of concentrated practical intervention by the police and their local organizational partners. Offers of standard issue Neighborhood Watch are unlikely to be sufficient. Progressive police services and their partners recognize this, and innovative and sustained efforts to achieve community participation can be found in such places. These may help create the “collective efficacy” that both increases the prospects of Neighborhood Watch and reduces the need for it. The best-documented example probably comes from Chicago’s community policing initiative.

There were early signs that the optimism engendered by face validity of Neighborhood Watch was not justified. Yet the promotion of schemes continued. Once having taken root, with high levels of public support, they were unlikely to be abandoned quickly. Neither politicians nor the police could pull the plug on the support they had given. As an overall movement, Neighborhood Watch has been easier to seed than to scuttle, even though individual schemes have tended to be short-lived as active entities. If anything the lesson from Neighborhood Watch for politicians and the police is to be wary of adopting too quickly what is popular and superficially sensible. There is a strong risk otherwise of being burdened with costly obligations that yield few if any real benefits. It would be prudent to run small, well-evaluated field trials before deciding whether to adopt schemes more widely and what shape such schemes should take.

Final Thoughts

The idea that the community should play a part in controlling crime and antisocial behavior is not new. Indeed the notion that the police are competent to do this without community participation is implausible. Members of the community are critical to reporting crime, to providing evidence that the police can follow up, to presenting evidence in court, to applying informal social control to those who might otherwise offend, to taking reasonable precautions to reduce their own risks of crime, and to providing a degree of guardianship to those about them, in particular in their residential neighborhoods. Much of this

happens without the need for any formal organization to make it happen. Where it does not occur spontaneously, then efforts to foster it make sense. Neighborhood Watch comprises a vehicle to refine and systematize community control processes. Many responsible citizens have been happy to be seen to cooperate in crime control by joining in the interests of themselves and their fellows. It is possible that marginal benefits may accrue, although these will be difficult to detect in low-crime neighborhoods because of a floor effect—there is not far for crime to fall, and in these circumstances, robust measurements of effectiveness become tricky. Where more than the formalization of informal processes is needed, more than offers of Neighborhood Watch are likely to be needed, to create conditions in which the routine crime control processes in low-crime neighborhoods can be fostered. This is likely to call for police and partnership activities that may include the establishment of Neighborhood Watch as part of it. Cocoons of the sort established in Kirkholt may comprise a suitable starting point where the practical purpose is clear. Even where local offenders may be among the victimized or their neighbors, their mobilization in the interests of social control might be beneficial both in sensitizing the offender to the effects crime has on victims and in the specific skills and knowledge they would bring to crime control. Any such moves, though, would need to proceed cautiously with systematic assessments for intended and unintended consequences that should guide policy and practice.

NEW DEAL FOR COMMUNITIES

New Deal for Communities (NDC) refers to a major area-based regeneration program aimed at improving the quality of life of residents in 39 disadvantaged English neighborhoods. Its primary objectives were to tackle, simultaneously, factors that most impact on quality of life, namely, poor job prospects, high crime, educational underachievement, poor health, and the poor quality of housing and physical environment in these communities. This entry describes the innovative approach adopted by NDC and its impact on crime.

The Program

NDC areas were small in size, with an average population of 11,000 residents, but the resources channeled into them, at around £50 million per area, were large compared with other area-based initiatives. The novelty of the NDC approach was its 10-year time horizon, its involvement of local communities in identifying priorities and policy interventions, and its cross-cutting approach to tackling local problems and improving residents' quality of life.

The juxtaposition of social and situational crime prevention measures (target hardening, closed-circuit television, and youth diversion) alongside education and training schemes (literacy programs and after-school clubs), public health projects (health advice and mental health projects), housing initiatives

(neighborhood management and physical improvements), employment initiatives, and anti-poverty strategies within a single program was highly innovative. This was new: a holistic approach to regeneration across a relatively long time horizon. It represented a genuine attempt to shift power to local communities, to break the "silo approach" to policy making and to avoid the damaging effects of short-term regeneration policy delivery.

Better Information

An important legacy from NDC will be its evaluation, which has seen the consolidation and cross-referencing of secondary data covering each policy domain. For the first time, a database of disaggregate recorded crime data was assembled for the whole of England from information supplied by 39 police forces. This has facilitated the search for crime displacement and the diffusion of benefit (i.e., added reductions in crime) in areas immediately adjacent to NDC schemes. Where changes in NDC crime levels occurred, these were much more likely to be accompanied by diffusion of benefit than by crime displacement, raising the possibility that falling crime in NDC areas may have spread to neighboring areas creating a "halo effect."

Data on the circumstances and views of NDC residents (some of it longitudinal) were captured through three extensive household surveys ($N = 19,000$). These contained questions on health status, educational attainment, income levels, housing conditions, employment, perceptions of crime and victimization, and self-assessed quality of life.

Thus, interrelationships between different problem and policy domains could be explored. The correlation between worry/fear of crime and risk of victimization was shown to be weak. In several NDC areas, residents' anxieties about crime were far greater than their risk of being a crime victim. For example, Haringey in Greater London had one of the highest levels of anxiety about crime but was among the lowest areas on self-reported victimization. In Brighton, people were far less worried than their level of risk might suggest.

If the problem is one of worry about crime and not risk, then reducing crime may not be reflected in reductions in anxieties about crime. In situations where residents are worried and fearful, then reassuring them may be more effective than trying to reduce crime.

More significantly, the NDC survey made it possible to identify the relative importance of different factors in determining residents' quality of life, satisfaction with their neighborhood, and the perceived suitability of areas for bringing up children. Interestingly, personal debt and health had a greater impact on self-assessed quality of life than victimization. Perceptions of crime were more important than either the area crime rate or personal victimization in explaining variations in neighborhood satisfaction. Finally, perceptions of minor crime and disorder were the most important factors in assessing how suitable an area was for bringing up children. Surprisingly, fear of crime was much further down the list of salient influences.

New Thinking

The NDC initiative has raised the awareness of policy makers of the interconnectedness of urban problems, namely, the fact that the most disadvantaged areas often have concentrations of offenders and relatively high crime; higher morbidity and lower life expectancy; poorer educational attainment; an absence of job opportunities; substandard, unaffordable, and poorly managed housing; lack of open space; leisure and shopping facilities; and so on.

Thus, questions around the crime reduction effects of job creation, the extent to which regeneration reduces crime, and the health impacts of an effective crime prevention program, have become relevant. Evaluation research published in 2008 suggests that policy interventions in one outcome area may well have benefits for other outcome areas. The findings reveal that as the housing and physical environment of NDC areas improved, crime rates reduced, and that as unemployment decreased health, outcomes improved.

Pondering the relationship between regeneration and crime and vice versa raises some interesting questions and pinpoints potential areas for continued research. Traditionally, area-level crime reduction has been viewed in terms of measures specifically targeting crime, such as situational prevention, surveillance and guardianship approaches, policing initiatives, prolific offender, and repeat victimization strategies. An advantage of the NDC approach is that it encourages one to think of "neighborhood crime reduction" in the same terms as one approaches an individual's propensity to offend or to desist

from crime, namely, as an outcome of a plethora of influences spanning several policy domains.

NONREPORTING/FAILURE TO REPORT VICTIMIZATION

Being a victim of violent crime will likely be a traumatic event. Coupled with the victimization trauma is the distress of recounting the victimization to others. The process of reporting and to whom victims report has been researched extensively. Some victims' pattern of disclosure is to third parties outside of the formal criminal justice system (e.g., friends and family members), whereas others may report to a variety of social agents (e.g., police, doctor, or counselor). Within the criminal justice system, reporting may include many agents, specifically the police, court officials, and possibly victim service representatives. Although reciting the victimization is challenging, reporting is crucial on numerous levels. First, absent reporting to the police or other official form of social agent,

necessary victim assistance services may not be made accessible. Second, if a victim fails to report, then the perpetrator will be unable to be apprehended and the potential to deter future crimes will be thwarted, potentially leaving other communities and individuals in harm's way. Last, reporting crime allows for analysts and organizations to get an accurate picture of crime prevalence, thus guiding proper resource allocation. In turn, accurate measures of crime victimization provide insight into developing relevant policy initiatives.

Since the 1970s, a rich body of research has evolved to offer some explanation as to why victims fail to report. This research has often focused on specifics of the relationship, that is, whether the defendant was a stranger or a nonstranger. Generally when offenders were relatives, intimates, or acquaintances, victims are often less likely to report the events than if the offender was a stranger. Historically, research suggested that the gap differential in the likelihood of police notification between these two groups is significant. Based on contemporary legal, political, and cultural reforms, however, some speculate that this gap is closing, whereas others do not. In regard to reporting procedures for known offenders of personal crimes such as sexual assaults, a multitude of research suggests these crimes are often not officially reported. Specifically, national data reveal that the majority of female rape and sexual assault victims between the ages of 16 and 24 years do not report their victimization. This entry summarizes reporting research detailing certain constraints related to individual and social characteristics.

Measuring Victimization

Although unreported personal crime has impacts on victims and society at large, gaining insight on accurate reporting of victimization is challenging. Using national data sets, the extent of reporting to police ranges from 40% for nonsexual crimes, up to 50% for physical assaults, and up to 75% domestic violence. Using other prevalence measures, research has found 50% of sexual crimes go unreported and up to 93% of college sexual victimizations are not officially reported.

For example, when surveying domestic violence victims, research has found that victims are less apt to report when the perpetrator is known. However,

research on a national data set found that the victim-offender relationship for domestic violence had no effect on reporting. Some suggest that this discrepancy could be from methodological errors related to the reporting instruments themselves. That is, the victim may not perceive specific acts to be criminal in nature and, therefore, refrain from reporting caused by not viewing themselves as a victim.

Barriers to Reporting

Research suggests that prior to reporting a crime there are complex and interrelated factors that a victim must consider. Generally, these factors include the victim's motivation to report the crime based on the seriousness of the event, as well as what their confidence of formal sanctions being imposed will be, and last, fear of offender reprisal. There are also other barriers to reporting a crime that are specific to certain individual and structural characteristics.

Gender Effect

Studies have shown that the risk of victimization is greater for males than for females. Furthermore, men are more likely to be victims of personal crimes such as robbery and assault. Studies have also shown that these victimizations are often not random but seem to be a function of a person's lifestyle and routine activities. Specifically, men of a certain age are more likely to partake in activities that take them into public places at night, which increase their risk to be a victim. Police notification in these types of crime, although underreported if they know the assailant, tend to be reported more than other crimes. Although men are proportionately more likely to be a victim, most research indicates a much higher nonreporting rate of personal violent crimes such as rape/sexual assault. Since the 1970s, social science researchers and feminist scholars backed by empirical science have repeatedly shown that rape, particularly those by known assailants, is a hidden epidemic underrecognized by the legal system. Although this is accurate, there may be an additional obscured fact that most of the nonreporting literature focuses on male perpetrated violence among females.

Reporting rates for male victims might be even lower given men's need to maintain their hegemonic status. Men may sometimes be reluctant to

report interpersonal violence because of a fear of being labeled as “less of a man.” They may also fear that others will not believe they really experienced victimization. Additionally, there are very few domestic violence shelters and interpersonal violence support groups available to men.

Another gendered effect could be if the crime was committed by a same-sex partner. Research has found that gay males experience extreme levels of physical violence; yet they are reluctant to report. Specifically, many gay and lesbians fear that if they report the crime, they will be treated with indifference and insensitivity.

Victim–Offender Relationship

Research has highlighted the need to address certain extralegal factors such as the status of the victim–offender relationship. Specifically, research focusing on domestic violence, in particular, has found that marital status is a critical factor in the parties’ decision to notify the police. For example, cohabitating or unmarried individuals were more likely to report than those who were married. Time in the relationship was also a predicting factor for some; that is, those in newly formed relationships were more likely than those in more established relationships to report the incident.

Race

Research has reported that there may be a race barrier to reporting violent crimes. That is, people not in the majority race may be reluctant to report violent crimes because of a mistrust of systems that have historically been used to oppress and exploit them. Some research reports individuals of different races having a higher risk of victimization, which in turn can affect prevalence rates if they are more resistant to report. For example, Hispanics are more likely to be the victims of robbery and aggravated assault than non-Hispanics, according to national statistics. American Indian women experience more rape, by both strangers and intimate partners, than other U.S. racial and ethnic groups, according to a national study. Finally, some purport that the high risk of victimization for minorities might be caused by their tendency to reside in socially disadvantaged communities.

Social Economic Status

Research has found that violence against those who reside in suburbia is reported to police at rates lower than violence against those in urban environments. This research, however, is not consistent. Some findings suggest that those residing in wealthier neighborhoods and who own their own homes are more likely to report than a renter would. Other research provides structural barriers as to why victims do not comply with reporting, that is, when public transportation is not available and may be a significant barrier to accessing system services (e.g., court dates). Another consequence research has found in regard to social economic status is with profound poverty and isolation. That is, the lack of common resources such as telephones and safe homes precludes some from reporting to the police.

Immigration Status

Some research has reported that cultural differences and language barriers impact an individual’s decision to report an incident. The rationale for not reporting specific to immigration issues includes undocumented immigrants being fearful of deportation. Abusive partners often control their victims by threatening to have them deported or by refusing to file for their legal immigration status. Furthermore, it might be difficult to communicate information directly in ways that may not be offensive to an individual’s value system. That is, reporting agents (e.g., law enforcement personnel, advocates, and health care providers) all make recommendations based on the values of the majority U.S. culture that may clash with the victim’s values.

People who lack lawful permanent residency may not know that they have the same rights as lawful U.S. residents if they are victims of crime. In estimating the underreporting of crime among foreign-born immigrants, research found that a large proportion of their sample, including police chiefs and district attorneys of the 50 largest U.S. cities, cited underreporting of immigrant victimization. Overall, Hispanic and Asian ethnicities were most commonly believed to underreport their victimization.

Disabilities

Persons with disabilities may be afraid or unable to report incidents of victimization. Often, the abuser

of a person with disabilities is also the primary caretaker. This arrangement makes it even more difficult for that individual to report abuse to the police.

Prejudice and Victim Blaming

Victims are motivated to report the incident if they expect reporting would result in a positive outcome, such as an arrest. However, substantive research has reported that many women did not disclose violence, even when social agents knew of the violence. The rationale for this includes some victims reporting negative experiences with hospital providers, stating they showed superior attitudes and used confusing terminology. For the crimes of rape, assault, and motor theft, a large percentage of the victims reported that the victimization was “a private matter” and that police would not be effective. Victim complicity is also discussed as a reason why some victims fear reporting the crime, since they might be accused of a crime themselves. If the victim had consumed drugs or alcohol, they might fear being blamed for the incident.

Severity of Violence

Notwithstanding the barriers to reporting listed above, research suggests that severity of violence (e.g., weapon or gun present and injury) is a predictor of whether police are contacted. That is, research has shown the more severe the violence, the more likely to report. The exception to this is in the case of sexual assault and rape. Even with the presence of violence, this is the most underreported crime.

Future Reporting Strategies

The extensive reporting research has found that it is relevant to understand when victims report or fail to report a crime. In particular, acknowledging these barriers to inform the development of policy initiatives, resource allocation, and victim safety is significant. Keeping in mind the victimization event might be traumatic, it is important to realize that each individual may experience violence and the effects of violence differently. Thus, it is critical that the justice system responds to reporting procedures acknowledging the barriers presented above and attempt to remove structural barriers. Continuing to create a climate that allows victims to

feel safe, and reducing structural reporting barriers (e.g., reducing the initial need to repeat event), can foster an environment that victims feel a comfort level and respect to be able to report without recourse.

In some jurisdictions, removal of restrictive reporting procedures has provided victims with the opportunity to disclose the details of the victimization confidentially without fear of reprisal or self-blame. In fact, when dealing with personal victimizations such as sexual assault, allowing the victim to weigh their options and seek guidance whether or not to participate actively in a criminal investigation has shown to increase overall reporting rates.

OCCUPATIONAL VIOLENCE

During the past three decades, several studies, notably in victimology, criminology, public health, management, as well as occupational and industrial medicine, have explored the link between different occupations and violent victimization. As a result, occupational violence is now recognized as one of the most serious occupational hazards, which can have dire consequences on the physical and psychological well-being of employees and can cause significant economic and social costs to organizations and the wider community. This entry briefly discusses the definitions and typologies of occupational violence as well as the sources of occupational violence statistics. Later on, via a review of the research, it identifies several features or characteristics of occupations that are likely to render employees more susceptible to violence.

Definitions

Despite almost four decades of research, governmental officials and researchers have not come up with a uniformly accepted definition of occupational (or workplace) violence. A lack of agreement exists concerning the definition of the terms *violence* and *workplace*. As far as violence is concerned, the definitions that have been proposed over the years form a continuum ranging from narrow ones, which include only physical assaults and injuries, to broad ones, which also include

nonphysical acts such as threats and harassment, intimidation, as well as verbal and psychological abuse. Similarly, some researchers adopt a constrained definition of workplace with data being collected only for incidents that take place in offices, stores, gas stations, restaurants, prisons, hospitals, and other physical settings. Other researchers, however, define the workplace more broadly allowing for mobile or geographically diverse occupational activities such as those conducted by drivers, police officers, firefighters, and journalists. These broader definitions of the workplace also take into consideration occupational groups whose jobs involve visiting people's houses, like plumbers, electricians, and postal officials.

No clear consensus exists regarding either the *source* or the *target* of the violent act in the workplace. Early definitions of occupational violence recognized only individuals as perpetrators, ignoring the possibility that whole groups of people or even organizations may be the source of the violent act. Those early definitions recognized as the main source of occupational violence external perpetrators who have no legitimate relationship to the workplace (such as thieves or burglars). Later definitions include customer- and client-related occupational violence as well as staff-on-staff violence and violence caused by an employee's spouse or other family member. Furthermore, occupational violence is defined without consideration of the attacker's intent in order to be able to cover situations where the source of violence is a person who may not be able to form intent but who is capable of violence (e.g., a patient with a brain

injury unable to make conscious decision). Several researchers, nowadays, also recognize that the source of violence may as well be a whole group of people (such as those protesting in a violent way against an organization's policies or practices) or the organization itself (e.g., an organization that knowingly places workers in dangerous or violent situations). As far as the target of the violent act is concerned, early studies focused primarily on individuals and ignored any violent act against their property. Researchers nowadays try to estimate not only the level of an individual's physical injury but also the potential psychological impact of a violent act against his or her property (e.g., damage or theft).

Several definitions quoted below confirm the above and illustrate the fact that the concept of occupational violence is not only historically but also socially and culturally contingent. Thus, for example, the European Commission provided in 1994 a broad explanation that encompasses a wide range of violent actions by defining workplace violence as involving "incidents where persons are abused, threatened or assaulted in circumstances related to their work, involving an explicit or implicit challenge to their safety, well-being or health" (Wynne, Clarkin, Cox, & Griffiths, 1997, p. 1). On the other hand, the National Institute for Occupational Safety and Health in the United States defined workplace violence in 1996 as "violent acts, including physical assaults and threats of assault, directed toward persons at work or on duty" (p. 6). In Australia, the National Occupational Health and Safety Commission defined occupational violence in 1999 as "the attempted or actual exercise by a person of any force so as to cause injury to a worker, including any threatening statement or behaviour which gives a worker reasonable cause to believe he or she is at risk" (p. 4). Meanwhile, the Australian Capital Territory (ACT) Occupational Health and Safety Unit incorporates property violence into its definition by stating that "occupational violence is any incident in which employees are threatened or assaulted in circumstances arising out of their work. This may include personal intimidation in the form of threatening phone calls received at work or at home and vandalism to personal property" (p. 2). Finally, the International Labour Organization (ILO) defined workplace violence in 2003 as "any action, incident

or behaviour that departs from reasonable conduct in which a person is assaulted, threatened, harmed, injured in the course of, or as a direct result of, his or her work" (p. 4).

Types of Occupational Violence

Researchers usually accompany their definition of occupational violence with a detailed description of the types or sources of this violence. As mentioned, there is no consensus among researchers and governmental officials as to how many types or sources of occupational violence should be identified. However, the types of occupational violence most commonly used nowadays are as follows:

1. *Criminal or intrusive violence*: Violent acts by criminals who have no legitimate relationship to the business or its employees and are usually committing a crime (e.g., robbery) from which violence derives.
2. *Customer-related violence*: Violent acts by people who have a legitimate relationship with the business and become violent while being served (e.g., customers, clients, patients, students, and inmates).
3. *Co-worker violence*: Violent acts by an employee (or past employee) of the business or contractor (working as a temporary employee) who attacks or threatens another employee.
4. *Domestic violence at work*: Violent acts by someone who has a personal relationship with an employee and threatens or assaults the employee at the workplace (e.g., family member or boyfriend/girlfriend).
5. *Organizational violence*: Violent acts committed by the organization against staff or customers.

Occupational Violence Statistics

Accurate information about the true extent of occupational violence is not yet available. With the exception of fatal incidents, which represent a very small portion of the overall violent incidents in the workplace, all other types of violence at work remain underreported. Researchers estimate that approximately only one in five incidents are formally reported and argue that organizational culture, job

insecurity, embarrassment, and severity of the act influence the victim's decision to report occupational violence. Typically, the less severe incidents are less likely to be reported and insecure workers are generally less willing to report violent acts because of job loss fears.

The identification of clear trends is also impeded by the lack of a uniformly accepted definition among researchers about the nonfatal occupational violent acts. As mentioned, most researchers include in their survey instruments only physical acts of violence that result in an injury and ignore incidents of nonphysical violence such as threats, intimidation, as well as verbal and psychological abuse. Furthermore, not all of the aforementioned types of occupational violence are included in a survey. As a result, many types of occupational violence are virtually underinvestigated. The British Crime Survey, for example, measures only criminal (or intrusive) violence in the workplace and excludes cases of domestic violence and violence between colleagues. On the other hand, the Survey of Workplace Violence Prevention implemented by the U.S. Bureau of Labor Statistics includes all types of occupational violence except for the organizational one.

The discussion that follows provides some baseline data about occupational violence in selected Western industrialized countries and identifies occupations more at risk of suffering violence. Overall, the data indicate that the high-risk occupations are similar across most countries. However, the research evidence is far from providing firm and clear answers. To the problems already mentioned, we should add the fact that patterns of employment (e.g., working hours, work shifts, and proportion of self-employed individuals) and structural factors, such as labor laws or firearm access, vary from country to country and between industries and occupational subgroups. An additional complication stems from the level of information provided by victimization surveys. Most of those surveys do not assign a Standard Occupational Classification code to classify workers into occupational categories. The National Crime Victimization Survey, for example, measures occupation in only six different areas (medical profession, mental health services, teaching profession, law enforcement or security field, retail sales, and transportation). On the other hand, studies that use a Standard Occupational Classification code,

like the Survey of Occupational Injuries and Illnesses of the Bureau of Labor Statistics, usually do not include detailed measures of all types of occupational violence.

Industries and Occupations Where Violence Is More Common

Research conducted in several Western industrialized countries indicates that acts of violence are not spread evenly across all workplaces. Violence tends to occur around work settings with specific risk factors that render employees more susceptible to victimization.

Type 1. Criminal or Intrusive Violence

Researchers in the United States, Australia, the United Kingdom, and Canada have identified five core risk factors common to the occupations at highest risk of crime-related (or instrumental) violence: employees exchange money or other valuable goods, work alone or in small numbers, work late at night or during early morning hours, have face-to-face contact with the public, and guard valuable property or possessions. Occupations frequently identified as having elevated risk of criminal violence are taxi drivers and chauffeurs, convenience store operators, gas station attendants, bus drivers, sales counter clerks, delivery workers, as well as cashiers and workers at amusement and recreational posts. Taxicab drivers and chauffeurs, for example, have one of the highest rates of work-related homicides and assaults across all Western countries. In the United States, it has been estimated that taxicab drivers and chauffeurs suffer 17.9 fatalities per 100,000 workers, or 36 times the risk of all employed individuals. In Australia, the assault rate on taxi drivers was approximately 10.4 per 100,000, and the taxi drivers were 27 times more likely than the general public to be assaulted and 66 times more likely to be robbed. Drivers are also frequently subject to rude gestures and offensive racial or sexual comments.

Type 2. Customer-Related Violence

Customer- (or client-) related violence is one of the most common types of violence in the workplace identified in almost all industrialized countries. The core risk factors of this type of violence

are employees working with unstable or volatile persons, having a mobile workplace, having face-to-face contact with the public, working in high-crime areas, working alone or in small numbers, and working in community-based settings. In both the United States and the United Kingdom, the occupations at high risk for client-related violence are police officers and prison guards, security personnel, mental health professionals, teachers in special education, and nurses. A similar pattern exists in Australia as well with miscellaneous laborers, social workers, community welfare workers, and prostitutes also being among the most at-risk occupations.

Type 3. Co-Worker Violence

The potential of co-worker violence is mainly influenced by highly competitive organizational cultures and management styles that fail to maintain equitable workloads and stability among workers. Poor working conditions, insecure jobs, and the possibility of unemployment also increase the potential for violence because they elevate stress levels and foster resentment and anger among employees. The research so far indicates that occupations in the goods-producing industries usually report a higher percentage of co-worker violence than occupations in the service-providing sector. Most violent incidents involve repeated bullying, threats, verbal or physical abuse, and stalking. The incidents may occur between a supervisor and an employee or between two employees of the same level. The incidents may involve multiple perpetrators and multiple victims, and the violent acts may be repeated over time.

Type 4. Domestic Violence at Work

Worksite accessibility and management tolerance of alcohol and drug use affect the spillover of domestic violence in the workplace. Other risk factors are employees with a history of violence, episodes of violent behavior outside the workplace, and employees who have recently experienced stressful events at home (financial difficulties, accidents, etc.). The research in the United States and Australia indicates that domestic violence in the workplace targets women significantly more often than men and that

occupations in the service-providing sector report much higher percentages of domestic violence than occupations in the goods-producing sector.

Type 5. Organizational Violence

Organizational violence is the least researched type of occupational violence. Scarce research evidence indicates that precarious employment, insecure jobs, quasi-military hierarchical and rigid management styles, highly competitive business environments, and severe economic downturns are the core risk factors of this type of workplace violence. Evidence about the more at-risk occupations of this type of violence is not available yet. However, research conducted in Australia indicates that organizational violence is usually systemic across whole sectors of the economy, concentrating particularly within industry subgroups or geographical areas where unemployment is a major problem.

Table 1 summarizes the above discussion about the sources of occupational violence, the risk factors, and the occupations where violence is more common.

Table I Summary of the discussion about the sources of occupational violence, the risk factors, and the occupations where violence is more common

<i>Sources of Occupational Violence</i>	<i>Types of Crimes Commonly Committed</i>	<i>Risk Factors Commonly Identified</i>	<i>Most Vulnerable Occupations Identified</i>
Source 1: Violent acts by criminals who have no other connection with the workplace or the victim but enter only to commit crime.	• Homicide • Armed robbery • Aggravated assault • Robbery • Simple assault • Battery	• Exchange of money or other valuable goods • Working alone or in small numbers • Working late at night or during early morning hours • Having face-to-face contact with the public • Guarding valuable property or possessions	• Taxi drivers and chauffeurs • Convenience store operators • Gas station attendants • Sales counter clerks • Bus drivers • Delivery workers • Cashiers (in banks, post offices, etc.) • Retail sales staff • Amusement and recreational workers
Source 2: Violence directed at employees by customers, clients, patients, students, inmates, or any others for whom an organization or a professional provides services.	• Homicide • Aggravated assault • Simple assault • Battery • Attack • Verbal abuse • Threats • Sexual harassment	• Working with unstable or volatile persons • Having a mobile workplace • Having face-to-face contact with the public • Working in high-crime areas • Working alone or in small numbers • Working in community-based settings • Having an easily accessible worksite	• Police officers • Security personnel • Nurses • Detectives • Prison guards • Mental health professionals • Social workers • Emergency department workers • Community welfare workers • Firefighters • Teachers • Prostitutes
Source 3: Violence against co-workers, supervisors, or managers by present/former employee(s).	• Aggravated assault • Sexual/racial harassment • Simple assault • Battery • Cyber-harassment • Bullying • Threats/ intimidation • Mobbing • Verbal abuse • Vandalism • Rude/offending gesturing	• Organizational culture or management style conducive to injustice • Highly competitive business environments • Failure to maintain equitable workloads • Insecure jobs • Workers facing unemployment • Poor systems design or work station architecture • Poor communications • Poor working conditions	• Occupations in the goods-producing sector usually report a higher percentage of co-worker violence than occupations in the service-providing sector

(Continued)

Table I (Continued)

<i>Sources of Occupational Violence</i>	<i>Types of Crimes Commonly Committed</i>	<i>Risk Factors Commonly Identified</i>	<i>Most Vulnerable Occupations Identified</i>
Source 4: Violence committed in the workplace by someone who doesn't work there but has a personal relationship with an employee—an abusive spouse or domestic partner.	• Homicide • Aggravated assault • Simple assault • Battery • Stalking • Cyber-harassment • Harassing phone calls • Threats	• Alcohol and drug abuse • Accessible worksite • Recent episodes of violent behavior outside the workplace • Employees with history of violence • Home finance/ money problems • Stressful events at home (accidents, illnesses, etc.)	• Occupations in the service-providing sector report much higher percentages of domestic violence than occupations in the goods-producing sector
Source 5: Violence committed by the organization or business against staff.	• Abuse • Threats • Negligent or exploitative working conditions • Knowingly placing workers in dangerous or violent situations • Unreasonably excessive work demands or working hours • Discrimination on the basis of race, color, religion, sex, or national origin • Threats against continued or future contracts	• Precarious employment • Insecure jobs • Quasi-military hierarchical and rigid management styles • Highly competitive business environments • Severe economic downturns	• No available data yet

OFFENDER-BASED PROGRAMS

Each day, more than 7.3 million offenders are under some form of correctional supervision in the United States (1 out of every 31 adults), with approximately one third incarcerated and the remainder on probation or parole. Within the last 30 years, the number of incarcerated offenders has grown exponentially, to its highest level at 2.3 million. At present, the United States has an incarceration rate five times higher than any other Western country. Moreover, each year in the United States, 700,000 incarcerated offenders are released back into the community; however, many will not successfully make this transition. This “revolving door” has resulted in creating a process where two thirds of offenders will most likely be arrested within 3 years, and one half will be returned to prison for either parole violations or new charges. This entry examines offender-based programs currently being used in the United States.

Why Treatment Matters

Crimes caused by violent and nonviolent offenders create a substantial cost to society. In addition to the financial burden society must pay to prosecute,

confine, and rehabilitate offenders, the greatest pain and suffering is truly experienced by victims of the crime. Many offenders do not see the value in socially responsible behavior, either because it is not supported within their peer culture or because they do not receive the immediate or instant gratification they desire. Therefore, many offenders often undergo deconditioning (losing entrenched beliefs), followed by conditioning (learning prosocial behaviors) to learn the practice of self-regulation and self-management skills. Successful offender-based programming must address criminogenic needs to reduce recidivism in order to promote prosocial changes. Criminogenic needs can best be defined as dynamic risk factors that upon change reduce reoffending. Particular dynamic criminogenic needs effectively addressed in rehabilitation programs include antisocial attitudes, antisocial feelings, antisocial peer associations, and impulsivity. Scholarly research has determined that antisocial thinking or attitudes are among the strongest predictors for future recidivism among offenders.

It has been shown that three principles are necessary for effective offender treatment: risk, need, and responsivity. Specifically, these principles have all been found to impact the effectiveness of treatment. The risk principle maintains that effective treatment must match the risk level of the offender. To predict risk of recidivism, static and dynamic factors specific to the offender must be evaluated. Static risk factors are not changeable and include the details of an offender’s criminal history. Dynamic risk factors are changeable and include issues such as housing arrangements, employment, or attitudes. Offenders are matched to specific treatment programs based on their assessed risk. Specifically, offenders with a higher level of risk should be assigned to intense treatment and offenders with lower risk should be assigned to less intense treatment.

The need principle asserts that effective programs must meet the needs of the offender. This can be classified into two categories: criminogenic or noncriminogenic. Criminogenic needs include antisocial beliefs or feelings that are predictive of future recidivism. Noncriminogenic needs include mental health issues, such as self-esteem and anxiety, which are not predictive of recidivism. Programs that address only noncriminogenic needs do not reduce reoffending.

The responsivity principle focuses on individual characteristics specific to the offender and on characteristics specific to the treatment environment that can influence treatment. Appropriate treatment should fit the offender's learning style, intellectual ability, and psychological adjustment. An effective treatment environment ensures appropriate therapeutic relationship development and treatment approaches from which the offender will benefit most.

Current Types of Offender-Based Programs

Community Model of Resocialization

Community models incorporate evidence-based principles and practices of social learning and behavioral programs, such as empathy, encouragement of self-efficacy, effective modeling and reinforcement, self-regulation and self-management skills, relapse prevention programs, and resource provision. One of the most common interpretations of the community model is the therapeutic community (TC). This form of programming is often used for sex offenders, special needs populations, mentally ill offenders, and dually diagnosed offenders.

Cognitive-Behavioral Programming

The cognitive-behavioral approach is based on the theory of social learning. Social learning theory asserts that changes in thoughts can lead to changes in physical behavior.

Problem behavior is often rooted in modes of thinking that encourage and sustain that behavior. Permanent change in behavior requires change at the cognitive level (i.e., attitudes). There are two main types of cognitive programs: cognitive skills and cognitive restructuring, which use objective and systematic approaches of change. Cognitive skills training asserts that offenders have never learned or developed the necessary "thinking skills" required to be productive and responsible members of society. Offenders received systematic training in skills, such as problem solving, anger control, assertiveness, demonstrated empathy and understanding of others affected by one's decisions, and social skills for specific situations. Cognitive restructuring programs are founded on

the idea that offenders have learned destructive attitudes and thinking habits that lead them to criminal behavior, and that cognitive deficits and distortions characteristics of offenders are learned, not inherited. Specifically, cognitive restructuring programs challenge offenders' specific pro-criminal attitudes and replace them with new attitudes and ways of thinking. Overall, evidence suggests that violent offenders who have completed a cognitive-behavioral treatment program are 25% to 50% less likely to recidivate than offenders that have not completed a cognitive-behavioral program.

A common cognitive-behavioral offender program is anger management. Anger management training focuses on educating offenders on examining their patterns of thinking about situations in which they tend to respond with anger or violence. Programming strategies often focus on practicing scenarios to understand fully what elicits their anger and violence, and to learn to substitute inaccurate interpretations with nonhostile explanations of others' behaviors.

Sex Offender Treatment

At present, it is estimated that approximately 150,000 offenders are imprisoned for sex-related convictions, 40% for rape, and 60% for other sexual assaults such as lewd acts with children, fondling, molestation, statutory rape, indecent practices, and other related offenses. On average, convicted sex offenders represent 10% to 30% of the incarcerated offender populations. Most adult and juvenile sex offender programs use cognitive-behavioral and relapse prevention models for treatment. Sex offender treatment programs address deviant sexual arousal or interests, impulsivity, sexual preoccupation, pervasive anger of hostility, antisocial orientation, pro-offending attitudes, and intimacy deficits or conflicts in intimate relationships. In general, evidence suggests that cognitive-behavioral sex offender treatment can reduce recidivism by 15% to 30%.

Traditionally, civil commitment has been used for the secure treatment and incarceration of nonresponsible, nonculpable individuals such as the mentally ill or criminally insane. However, civil commitment is now being used to incapacitate violent sex offenders, commonly referred to as sexually violent predators (SVPs). At present,

19 states have created civil commit statutes that allow for the confinement and treatment of SVPs, and currently, there are more than 4,500 sex offenders being held under SVP laws in the United States.

Batterer Treatment

According to the National Crime Victimization Survey (NCVS), there are more than 700,000 non-fatal violent incidents of intimate partner violence, of which 85% is committed against women. Since the 1980s, domestic violence intervention programs have begun to treat batterers who are predominately male. The two predominant treatment programs are the Duluth model and cognitive-behavioral therapy (CBT). The Duluth model encourages batterers to address their attitudes about control, in addition to learning new strategies for dealing with their partners. Cognitive-behavioral therapy views domestic violence as a product of errors in thinking and focuses on implementing skills training and anger management to reduce intimate partner violence. In general, evidence suggests that the Duluth model and CBT only reduce batterer recidivism by 5%.

Mental Health and Drug and Alcohol Treatment

Offenders are more likely to have a mental illness than the general public. It is estimated that half of all incarcerated offenders have a mental illness. Evidence suggests that offenders who have a mental illness are more likely to have a substance abuse problem. In fact, 7 out of 10 incarcerated offenders with a mental illness also have a substance dependency or abuse problem (i.e., co-occurring disorder). In terms of treatment, offenders with mental illness are significantly less likely to complete treatment than offenders who report no history of mental illness. Conversely, evidence has shown that offenders with co-occurring disorders can benefit from treatment. Specifically, evidence indicates that offenders with co-occurring disorders who successfully complete treatment are less likely to recidivate or use substances when out in the community.

Relapse prevention therapy (RPT) is often used with offender and nonoffender populations. RPT uses a cognitive-behavioral approach to develop

an individualized plan that includes the rehearsal of alternative prosocial responses that are specific to the behaviors or circumstances that increase the risk of reoffending. Self-monitoring and the ability to anticipate problem behaviors are skills reinforced during treatment.

Another program frequently used by offenders with drug and alcohol problems is called the 12 Step Program. The 12 Step Program began with Alcoholics Anonymous (A.A.) in the 1930s to facilitate the recovery from addictive or dysfunctional behaviors. The 12 Step approach has also been expanded to include drug abuse and various other addictive or dysfunctional behaviors. Currently, 12 Step programs are available in most correctional settings.

Using Sanctions With Offenders

Sanctions are commonly used as an approach to modify offender behavior. The theory supporting using sanctions proposes that by using immediate and consistent penalties, offenders will be deterred from drug use or crime. Examples of sanctions commonly used are intensive supervision, home confinement, electronic monitoring, frequent drug testing, and drug treatment. Sanctions are most frequently used in drug court. In general, evidence suggests that drug court participants are less likely to be rearrested after the end of the program than offenders not enrolled in drug court.

Restorative Justice

Restorative justice is founded on the idea that the criminal justice system should focus on criminal behavior as an act against the individual or community rather than the state. Most often, the purpose of restorative justice is restoration of both victims and offenders, in addition to reparation of harm perpetrated against the wider community. Evidence indicates that restorative justice has low to low-moderate positive effects on reducing recidivism for adolescent and adult offenders.

Conclusion

Offenders create a substantial cost to society, both in the costs to prosecute, confine, and rehabilitate them and in the devastating emotional

and psychological impact their actions have on victims. However, evidence has found promising indications that offenders can successfully rehabilitate and transition back into the community. Offender-based programs need to adhere to the principles of risk, need, and responsivity in order to achieve maximum benefits for the offender, victim, and society.

OFFENDING AND VICTIMIZATION

Criminological research has consistently shown that offenders are much more likely than nonoffenders to be victims and that victims are much more likely than nonvictims to be offenders. In other words, victims and offenders are often the same individuals. For example, the 2006 sweep of the U.K. Home Office's Offending, Crime and Justice Survey found that, for 10- to 25-year-olds, 50% of offenders had also been victims of a personal crime in the past 12 months compared with 19% of nonoffenders; levels of offending were also higher among those who had been a victim compared with those who had not been a victim, 42% versus 14%. Furthermore, across numerous pieces of research, this *victim-offender overlap* holds for survey and police recorded data, for single and repeat victimization, for personal and property crime, for adults and juveniles, for males and females, and for different ethnic groups, and it has been found across time and space. Although research has clearly established the existence of this victim-offender overlap, we currently do not know enough about the ways in which victimization and offending influence one another.

Before looking at the possible causes of the victim-offender relationship it is worth briefly highlighting why there is currently a gap in our knowledge beyond that of a need for more systematic research. First, there is the division of labor within criminology itself, so that offending and victimization are often perceived as separate subfields of study. Second, there is understandable concern that linking victimization with offending could lead to victim blaming, even though not all victims are offenders or vice versa. Finally, there is the fact that popular and political discourses tend to perceive offending and victimization in simple binary terms with "bad" offenders and "good" victims; the linking of offending and victimization complicates what can otherwise be treated as an unproblematic issue.

Current Explanations

Current explanations of the victim-offender overlap can be simplified into three broad approaches that are by no means mutually exclusive. First, the victim-offender overlap is often found within social

circles. High victimization rates and high offender rates are often strongly correlated at the neighborhood level, and residents tend to commit offenses on others within their neighborhood, so that in many cases offenders will also be victims. Similar processes also tend to operate within smaller social units, such as groups of friends. So, teenagers tend to have friends with a similar level of delinquency to their own, and a polarization emerges between high-delinquency and low-delinquency friendship groups. Given that individual members of these delinquency groups are likely to commit offenses on each other as well as on others outside the circle, they tend to have an elevated rate of victimization. Related to social circles, some types of crime originate from sequences of interaction between people who are in an intimate relationship or are thrown together within a workplace or neighborhood. Power is infrequently balanced in these relationships, and normally one party will be the offender and the other the victim, but the positions may be reversed from time to time, and in rare relationships, each person may play the part of victim and offender equally often. Whenever crime originates in the context of an ongoing relationship, victimization and offending are likely to be linked closely.

Second, the same personal characteristics or social and environmental factors may give rise both to offending and to victimization. For example, most offending behavior carries the risk of serious adverse consequences, so that risk-taking as a personality characteristic is associated with offending. At the same time, a failure to take precautions makes many kinds of victimization more likely, so that risk-taking is also associated with victimization. In terms of social and environmental factors, there is good evidence, for example, that weak social bonds can be associated with offending. They might also be associated with victimization, because it is harder for those without relationships to protect themselves and their property than for those who are embedded in dense social networks. Thus, the same social and environmental factors that give rise to offending may also give rise to victimization.

Third, there is good evidence for a direct causal relationship running from offending to victimization. Young offenders in residential care or prisoners, as is well documented, are vulnerable to personal and property crime. Offenders may also

become vulnerable to retaliation by their victims and to vigilante attacks by local people on behalf of the wider community. Obviously the causal link may also run from victimization to offending, for example, because a victim of crime decides to retaliate. Furthermore, it is likely that a causal chain may run back and forth between victimization and offending, with each giving rise to the other in a form of vendetta. Another possibility, as in the case of child abuse, is that victimization in childhood has an adverse effect on personal development, increasing the likelihood that the childhood victim will become an adult offender.

Implications

Identifying the processes underlying the victim-offender overlap potentially has important policy implications; because many of the same factors that predict offending also predict victimization, it may be possible to develop simultaneously programs that reduce the risk of both. Schemes such as victim support and restorative justice need to deal with the reality of victims who are often themselves offenders, and where offending may be closely connected to their victimization.

Future Research

The growing body of empirical work indicating a significant overlap between victim and offender populations suggests that criminological theory and research need to be more attentive to the role of victimization in the explanation of offending and to the role of offending in the explanation of victimization as well as to the conditions under which these populations converge.

OPERATION CEASEFIRE/ PULLING LEVERS

Several jurisdictions have been experimenting with new problem-oriented frameworks to understand and respond to gun violence among gang-involved offenders. These interventions are based on the “pulling levers” focused deterrence strategy that focuses criminal justice and social service attention on a small number of chronically offending gang members responsible for the bulk of urban gun violence problems. Although the research evidence on the crime prevention value associated with the approach is still developing, the pulling levers strategy has been embraced by the U.S. Department of Justice as an effective approach to crime prevention.

Pioneered in Boston to halt youth violence, the pulling levers framework has been applied in many American cities through federally sponsored violence prevention programs such as the Strategic Alternatives to Community Safety Initiative and Project Safe Neighborhoods. In its simplest form, the approach consists of selecting a particular crime problem, such as youth homicide; convening an interagency working group of law enforcement practitioners; conducting research to identify key offenders, groups, and behavior patterns; framing a response to offenders and groups of offenders that uses a varied menu of sanctions (“pulling levers”) to stop them from continuing their violent behavior; focusing social services and community resources on targeted offenders and groups to match law enforcement prevention efforts; and directly and repeatedly communicating with offenders to make them understand why they are receiving this special attention.

The Boston Gun Project and Operation Ceasefire

The Boston Gun Project was a problem-oriented policing enterprise expressly aimed at taking on a

serious, large-scale crime problem—homicide victimization among young people in Boston. Like many large cities in the United States, Boston experienced a large sudden increase in youth homicide between the late 1980s and early 1990s. The project began in early 1995 and implemented what is now known as the “Operation Ceasefire” intervention, which began in the late spring of 1996. The working group of law enforcement personnel, youth workers, and researchers diagnosed the youth violence problem in Boston as one of patterned, largely vendetta-like (“beef”) hostility among a small population of chronic offenders, and particularly among those involved in some 61 loose, informal, mostly neighborhood-based groups. These 61 gangs consisted of between 1,100 and 1,300 members, representing less than 1% of the city’s youth between the ages of 14 and 24 years. Although small in number, these gangs were responsible for more than 60% of youth homicide in Boston.

The Operation Ceasefire “pulling levers” strategy was designed to deter violence by reaching out directly to gangs, saying explicitly that violence would no longer be tolerated, and backing up that message by “pulling every lever” legally available when violence occurred. Simultaneously, youth workers, probation and parole officers, and later churches and other community groups offered gang members services and other kinds of help. The Ceasefire Working Group delivered this message in formal meetings with gang members, through individual police and probation contacts with gang members, through meetings with inmates at secure juvenile facilities in the city, and through gang outreach workers. The deterrence message was not a deal with gang members to stop violence. Rather, it was a promise to gang members that violent behavior would evoke an immediate and intense response. If gangs committed other crimes but refrained from violence, the normal workings of police, prosecutors, and the rest of the criminal justice system dealt with these matters. But if gang members hurt people, the Working Group concentrated its enforcement actions on them.

When gang violence occurred, the Ceasefire agencies addressed the violent group or groups involved, drawing from a menu of all possible legal “levers.” The chronic involvement of gang members in a wide variety of offenses made them, and

the gangs they formed, vulnerable to a coordinated criminal justice response. The authorities could disrupt street drug activity, focus police attention on low-level street crimes such as trespassing and public drinking, serve outstanding warrants, cultivate confidential informants for medium- and long-term investigations of gang activities, deliver strict probation and parole enforcement, seize drug proceeds and other assets, ensure stiffer plea bargains and sterner prosecutorial attention, request stronger bail terms (and enforce them), and bring potentially severe federal investigative and prosecutorial attention to gang-related drug activity. The multitude of agencies involved in the Working Group assessed each gang that behaved violently and subjected them to such “crack-downs.” These operations were customized to the particular individuals and characteristics of the gang in question, and they ranged from probation curfew checks to U.S. Drug Enforcement Administration (DEA) investigations.

The Ceasefire crackdowns were not designed to eliminate gangs or stop every aspect of gang activity but to control and deter serious violence. To do this, the Working Group explained its actions against targeted gangs to other gangs, as in “this gang did violence, we responded with the following actions, and here is how to prevent anything similar from happening to you.” The ongoing Working Group process regularly watched the city for outbreaks of gang violence and framed any necessary responses in accord with the Ceasefire strategy. As the strategy unfolded, the Working Group continued communication with gangs and gang members to convey its determination to stop violence, to explain its actions to the target population, and to maximize both voluntary compliance and the strategy’s deterrent power.

A large reduction in the yearly number of Boston youth homicides followed immediately after Operation Ceasefire was implemented in mid-1996. A U.S. Department of Justice (DOJ)–sponsored evaluation of Operation Ceasefire revealed that the intervention was associated with a 63% decrease in the monthly number of Boston youth homicides, a 32% decrease in the monthly number of shots-fired calls, a 25% decrease in the monthly number of gun assaults, and in one high-risk police district given special attention in the evaluation, a 44% decrease in the monthly

number of youth gun assault incidents. The evaluation also suggested that Boston’s significant youth homicide reduction associated with Operation Ceasefire was distinct when compared with youth homicide trends in most major U.S. and New England cities.

Other researchers, however, have observed that some of the decrease in homicide may have occurred without the Ceasefire intervention in place as violence was decreasing in most major U.S. cities. Jeffrey Fagan’s cursory review of gun homicide in Boston and in other Massachusetts cities suggests a general downward trend in gun violence existed before Operation Ceasefire was implemented. In their analysis of homicide trend data for the 95 largest U.S. cities during the 1990s, Richard Rosenfeld and his colleagues found some evidence of a sharper youth homicide drop in Boston than elsewhere but suggest that the small number of youth homicide incidents precludes strong conclusions about program effectiveness based on their statistical models. In his examination of youth homicide trends in Boston, Jens Ludwig suggested that Ceasefire was associated with a large drop in youth homicide, but given the complexities of analyzing city-level homicide trend data, some uncertainty remained about the extent of Ceasefire’s effect on youth violence in Boston.

The National Research Council’s Panel on Improving Information and Data on Firearms concluded that the Ceasefire evaluation was compelling in associating the intervention with the subsequent decline in youth homicide. However, the Panel also suggested that many complex factors affect youth homicide trends and it was difficult to specify the exact relationship between the Ceasefire intervention and subsequent changes in youth offending behaviors. Although the DOJ-sponsored evaluation controlled for existing violence trends and certain rival causal factors such as changes in the youth population, drug markets, and employment in Boston, there could be complex interaction effects among these factors not measured by the evaluation that could account for some meaningful portion of the decrease. The evaluation was not a randomized, controlled experiment. Therefore, the nonrandomized control group research design cannot rule out these internal threats to the conclusion that Ceasefire was the key factor in the youth homicide decline.

Experiences With Pulling Levers in Other Jurisdictions

At first blush, the effectiveness of the Operation Ceasefire intervention in preventing violence may seem unique to Boston. Operation Ceasefire was constructed largely from the assets and capacities available in Boston at the time and deliberately tailored to the city's particular violence problem. The operational capacities of criminal justice agencies in other cities will be different, and youth violence problems in other cities will have important distinguishing characteristics. However, the basic working group problem-solving process and the "pulling levers" approach to deterring chronic offenders are transferable to violence problems in other jurisdictions. Several cities have begun to experiment with these analytic frameworks and have experienced some encouraging preliminary results. Consistent with the problem-oriented policing approach, these cities have tailored the approach to fit their violence problems and operating environments.

In East Los Angeles, a DOJ-sponsored replication of Operation Ceasefire experienced noteworthy difficulty keeping the social service and community-based partners involved in the interagency collaboration. However, the law enforcement components of the intervention were fully implemented and focused on two gangs engaged in ongoing violent conflict. The evaluation revealed that the focused enforcement resulted in significant short-term reductions in violent crime and gang crime in targeted areas relative to matched comparison areas. In Stockton, California, a quasi-experimental evaluation of the Operation Peacekeeper gang violence reduction intervention also found a significant decrease in gun homicide associated with the pulling levers approach. An interagency task force implemented a pulling levers strategy to prevent gun violence among Hispanic and Asian gangs in Lowell, Massachusetts. A quasi-experimental evaluation found that the Lowell pulling levers strategy was associated with a 43% decrease in the monthly number of gun homicide and gun aggravated assault incidents.

A quasi-experimental evaluation of the Indianapolis Violence Reduction Partnership found that the pulling levers strategy was associated with

a 42% reduction in homicide in Indianapolis. When compared with homicide trends in the nearby cities of Cleveland, Cincinnati, Kansas City, Louisville, and Pittsburgh, the evaluation found that Indianapolis was the only city experiencing a statistically significant decrease in homicide during the study time period. In Chicago, a quasi-experimental evaluation of a Project Safe Neighborhoods gun violence reduction strategy found significant reductions in homicides in treatment neighborhoods relative to control neighborhoods. The evaluation found that the largest effect was associated with preventive tactics based on the pulling levers strategy, such as offender notification meetings that stress individual deterrence, normative change in offender behavior, and increasing views on legitimacy and procedural justice.

There is less experience in applying the pulling levers approach to other problems. In High Point, North Carolina, a pulling levers strategy has been aimed at eliminating public forms of drug dealing such as street markets and crack houses by warning dealers, buyers, and their families that enforcement is imminent. The project employed a joint police-community partnership to identify individual offenders, notify them of the consequences of continued illegal activity, and provide supportive services through a community-based resource coordinator. A preliminary assessment of the pulling levers drug market intervention found noteworthy reductions in drug and violent crime in High Point's West End neighborhood.

P

PARENTS ANONYMOUS

Child abuse and neglect are serious public health problems that have implications for both families and society. Parents Anonymous is one of the nation's leading organizations that aim to reduce child maltreatment and strengthen families through the education and treatment of parents. This entry provides an overview of the Parents Anonymous program, focusing on the unique group model employed by the program, the services that Parents Anonymous provides to members, and the empirical evidence that demonstrates the program's effectiveness.

History and Mission

Parents Anonymous is the nation's oldest child abuse prevention and treatment program. The program was founded in 1969 in a joint effort by a single mother and a social worker who believed that if provided with the right resources parents had the best means to strengthen their families. Parents Anonymous began as a grassroots endeavor within local communities and steadily grew to a decentralized organization with hundreds of accredited affiliates operating both across the United States and internationally. In the United States, the Parents Anonymous national office and state offices share private and public funding that is used to provide services to members and raise public awareness on reducing child abuse. Since its creation, Parents Anonymous has provided services and treatment to millions of parents who

have sought help and support from the program. Today thousands of members are regularly involved in weekly meetings and receive counseling through the Parents Anonymous hotlines.

Parents Anonymous partakes in a wide variety of evidence-based and cost-effective programming aimed at preventing abuse and strengthening families. The organization is modeled after a self-help program that encourages parents to discuss their parenting concerns openly, recognize the need to self-reward positive behavior, and develop their own self-esteem and confidence as parents. Parents Anonymous targets the reduction of a full range of abuse including physical, emotional, and sexual abuse; physical neglect; emotional deprivation; and verbal assault. The program aims to accomplish this task by providing a nurturing and therapeutic service to its members at no charge to the consumer. The safe and supportive environment provided by Parents Anonymous groups allows parents to discuss candidly the emotional factors that can lead to abuse and stress and learn how to enjoy the responsibilities of parenthood.

The Group Model

Parents Anonymous employs a group model where members of the group set the agenda of the meetings and decide the content that will be discussed. Each week, the group meets at a designated time in a safe, nonthreatening location to discuss a wide range of parental issues such as discipline, communication, child development, and coping with stress. The topics addressed in the group sessions relate to

the specific needs and concerns of group members present, and any subject that pertains to a member's life is open for discussion. The Parents Anonymous group model aims to take advantage of adult learning styles by emphasizing the importance of addressing problem behaviors, practicing new behaviors, and providing positive reinforcement. Each group session is led by a parent leader and a professionally trained sponsor. Along with group members, the parent leader and sponsor are fundamental components of the Parents Anonymous group model.

The Group Member

Members of the program are self-referred or have been referred by social agencies, police departments, courts, or medical professionals. All parents or individuals in parenting roles who have concerns about their parenting skills and would like to receive support or information are welcome and encouraged to partake in Parents Anonymous meetings and trainings. The services are geared toward parents who are seeking assistance on their own and those who have experienced problems obtaining help from other social service agencies. The program provides an important resource to the community because it offers services to individuals who are distrustful of traditional mental health professionals, or are financially unable or embarrassed to seek other mental health services. Membership in the program is voluntary, and participants are not required to speak at the meeting or provide identifying information. Each member is notified at their first meeting that Parents Anonymous takes a strong stance against the abuse of children, and the organization is required by state law to report suspected child abuse or neglect. Unless the health or safety of a child is in question, all other aspects of the program are confidential.

The Parent Leader

Each Parents Anonymous group has a parent leader who is a member of the group and facilitates the discussion along with the professional sponsor. The parent leader's role is to promote leadership within the group and to encourage communication between group members. Often, the role of the parent leader is shared by multiple parents to allow all interested members to develop and strengthen

their leadership skills. The parent leader works closely with the sponsor to structure the weekly meetings and facilitate the group discussion. In 1995, Parents Anonymous created the National Parent Leadership Team (NPLT) from a group of parent leaders who wanted to increase their leadership responsibilities. The NPLT is responsible for providing training to parents and professionals and for raising public awareness on the program and child abuse prevention. Since the inception of the NPLT, state and local programs have also developed their own parent leadership teams.

The Professional Sponsor

In addition to the parent leader, each group has a sponsor who meets with the group weekly and facilitates the discussion. The sponsor is a professional volunteer with experience in social work, mental health care, counseling, or a related field. Parents Anonymous sponsors have knowledge on a wide range of family issues, which include child abuse, child development, and juvenile delinquency, as well as knowledge on available resources within the local community. The sponsor's role is to act as an accepting and nonauthoritarian group consultant and to provide a positive representation of mental health professionals. Sponsors encourage an informal relationship between themselves and group members by using their first names and sharing personal information about their own lives. Through this process and the partnership with the parent leader, the sponsor aims to change participants' attitudes toward mental health and social service professionals.

The Volunteer

Volunteers play a vital role in the daily operation of the Parents Anonymous organization. They are responsible for facilitating and organizing weekly meetings, managing the Parents Anonymous hotlines, providing child care services, and administering children services and programming. Volunteers also help to raise public awareness on child abuse prevention and treatment and work to increase services within the community to assist parents in strengthening their families. The thousands of volunteers who work across the globe providing their services at no cost help Parents Anonymous keep expenses to a minimum so they

can continue to provide information and training to parents at no charge.

The Group Meeting

At the weekly meetings, parents are encouraged to share personal information about themselves and openly discuss the circumstances in their lives that affect their parenting. Members are also encouraged to exchange contact information and phone numbers with other members so that they can provide each other with 24-hour assistance and create a social support network. Through the exchange of information, members can call for help in times of need as well as discuss their parenting successes. The goal of the weekly meeting is to create a safe and nurturing environment where parents can talk about their concerns without fear of rejection or ostracism. Group meetings are open ended, and parents are welcome to join the group at any time and participate as long as they would like. Each week, the group discusses factors occurring in the parents' lives and focus on praising members' successes and minimizing their failures. Members are encouraged to practice new behaviors in their homes and share the results with the group. By providing a nonthreatening atmosphere, the Parents Anonymous group aims to break the parents' cycle of not requesting help when needed.

Principles

The Parents Anonymous organization adheres to four guiding principles. The first principle is parent leadership. Parent leadership refers to the need for parents to recognize their problems, create ways to resolve their problems, and act as an example to others. The second principle is mutual support, which reflects the reciprocal relationship of support and assistance that exists between parents in the group. The third principle is shared leadership, which refers to the partnership between the parents and the group sponsor and the sharing of responsibility and leadership roles. The fourth principle is personal growth. Personal growth is achieved when parents are able to create long-term change in their lives by interacting with the group and addressing their parenting concerns in an accepting environment. Parents Anonymous places a heavy emphasis on strengthening families through

programming and training seminars that adhere to the principles of mutual support and shared leadership. By operating under these four principles, the program aims to break down barriers to change and prevent the cycle of family violence.

Children Services

Parents Anonymous also offers a wide range of specialized programming for children while their parents are engaged in their meetings. These programs promote the healthy development of children and include classes aimed at addressing problem-solving and social interaction skills, drug and alcohol awareness, and dealing with emotions. The goal of the specialized programs is to increase the children's self-esteem while reducing risk factors for delinquency. Child care is provided to children in areas where specialized programming is unavailable. In 1994, Parents Anonymous partnered with the Office of Juvenile Justice and Delinquency Prevention (OJJDP) with the goal of preventing and ending juvenile delinquency and child abuse problems in families. Together, Parents Anonymous and the OJJDP are working to bring the shared leadership-mutual support model to culturally and ethnically diverse communities throughout the United States in an effort to reduce known risk factors for delinquency.

Empirical Evaluations

Parents Anonymous uses evidence-based services that have been empirically supported through research. A 1976 study by the Behavior Associates demonstrates the effectiveness of Parents Anonymous. The Behavior Associates conducted a survey on 613 participants in the program and asked them a wide range of questions concerning their parenting experiences, attitudes, use of community resources, and the prevalence and seriousness of abuse in their household. The study found that parents who attended Parents Anonymous meetings showed a decrease in verbal and physical abuse and an increase in self-esteem, help-seeking behaviors, and using community resources. The results also indicate that participants in the program had a greater understanding of child development. Another study conducted by Anne Cohn also demonstrates the effectiveness of Parents Anonymous programming. Cohn's study examined case managers and their

assessment of clients during the start and end of services. Cohn found that case managers reported that individuals who participated in Parents Anonymous were more likely to have improved parental skills and knowledge of child development.

In 2003, the National Council on Crime and Delinquency (NCCD) began conducting a 3-year outcome evaluation on Parents Anonymous to assess whether participation in the program reduced child maltreatment. The study was conducted on 206 new participants to Parents Anonymous who were given interviews at their first month, second month, and sixth month in the program. The evaluation found that individuals who participated in the program had reductions in risk factors that can lead to abuse and neglect and had a reduced likelihood to mistreat or act aggressively toward their children over time. Respondents also reported experiencing less stress, intimate partner violence, and drug and alcohol use. The NCCD report suggested that parents who continued to participate in the program were more likely than those who stopped attending meetings to improve on several outcome measures. Another encouraging finding from the evaluation is that individuals who began the program with the highest risk of child maltreatment improved significantly on every outcome measure.

The findings from the various evaluations demonstrate that the Parents Anonymous program can be used successfully to reduce the prevalence of child maltreatment and provide parents with the skills needed to be successful parents. Through the reduction of the risk factors that lead to child abuse and neglect, Parents Anonymous aims to strengthen families while reducing the frequency of other costly social problems that can result from child maltreatment.

PARRICIDE

Parricide technically refers to the killing of a close relative. Beginning in the early 1980s, the term has increasingly been used to refer to the killings of parents. *Matricide* denotes killing one's mother; the killing of one's father is known as *patricide*. The killing of one's parents has evoked horror since antiquity. These events often generate intense public interest because people are stunned when the victim is a parent murdered by their own offspring. Media accounts falsely suggest that parricide is common, typically involves multiple victims and offenders, and is largely committed by youth. This entry summarizes the incidence of parricide, which includes its offense as well as victim and offender characteristics; it also examines youth involvement in parricide using U.S. arrest data.

Incidence

Murders of parents are rare events in the United States. An analysis of murders reported to the Federal Bureau of Investigation (FBI) revealed that in 2005, of 14,680 total homicide victims, 123 were identified as mothers and 118 as fathers who were slain by their biological children. Combined, the killings of parents represented less than 2% of all

homicide victims and approximately 3% of homicides in which the victim–offender relationship was known. Studies have also concluded that parricide is a rare event in other countries, comprising less than 4% of all homicides in Canada and about 2% to 3% of all homicides and attempted homicides in France.

Victim, Offender, and Offense Correlates

Empirical analyses of national databases involving homicides in which children have killed parents have been limited. One of the earliest statistical analyses that involved parents as victims in the United States, undertaken by Kathleen Heide, used the FBI's Supplementary Homicide Report (SHR) data for the 10-year period 1977 to 1986. An updated examination of the characteristics of victims, offenders, and offenses in parricide incidents using SHR data for the 24-year period 1976 to 1999 was completed by Heide and Thomas Petee. They constructed two databases, which consisted of 5,781 victims and 5,558 offenders. Their findings, when compared with earlier ones, revealed that the correlates of parricide, when analyzed from arrest data across more than two decades, are amazingly stable over time. Highlights of these findings are summarized below.

Fathers and mothers slain by their children were typically killed alone by one offspring. In the offender-based data set, 92% of offenders killed mothers and fathers in single-victim, single-offender incidents. In the victim-based data set, 86% of parents were killed in this way.

Parricide Victim Characteristics

Victims killed in incidents in which mothers were slain ranged in age from 28 to 98 years of age and older; the age range for victims killed in patricide incidents was nearly identical, from 27 to 98 years of age and older. The mean and median ages of victims killed in matricide incidents were 58 and 57 years, respectively. Victims in patricide events were slightly younger than victims in matricide events. The comparable average ages for victims killed in patricide events were 55 and 53 years, respectfully.

Significant racial differences emerged in parricidal incidents that involved fathers and mothers. Victims killed in matricide events were significantly more likely to be White than non-White when compared

with victims killed in patricide events. In matricide incidents, 75% of victims were White, 23% were Black, and approximately 2% was composed of Oriental, Indian, another racial group, or unknown race categories. In patricide incidents, 68% of victims were White, and 30% were Black; the remaining 2% was composed of the four other categories.

Parricide Offender Characteristics

Offenders involved in incidents in which mothers were killed ranged in age from 8 to 78 years of age; offenders involved in patricide incidents ranged from 7 to 72 years old. The mean and median ages of offenders who participated in killing mothers were 30 and 27 years, respectively. Offenders involved in patricide events tended to be slightly younger; the comparable ages for these offenders were 25 and 23 years, respectively. The racial profile of offenders was similar to the racial profile of victims killed in parricide incidents. Offenders involved in the killings of mothers were significantly more likely to be White than those involved in the killings of fathers.

Significant differences were found when the gender of the offender was examined. In most of cases, sons were the killers in both matricide and patricide events. Males were involved in the murders of 84% of the incidents involving mothers and 87% of the incidents involving fathers.

Youth Involvement in the Slaying of Parents

Significant differences emerged when the ages of offenders involved in killings of mothers and fathers were examined. The age distribution of offenders involved in killing fathers was more restricted than that found in incidents involving mothers. More than 72% of patricide incidents were perpetrated by offspring less than 30 years of age, compared with 56% of matricide incidents.

During the 24-year period under review, most offenders involved in incidents in which fathers and mothers were killed were adults. However, juvenile involvement in parricidal incidents is worth noting. One of six offenders who participated in the killings of mothers (17.0%) was less than 18 years of age. In patricidal incidents, one of four offenders (25.4%) was a juvenile. The involvement of youth in U.S. parricide incidents is substantial when the

analysis is extended to include the upper end of adolescence, 18 and 19 year olds. Offenders younger than age 20 years were involved in one quarter of incidents in which mothers were slain (25.0%) and more than one third of incidents in which fathers were killed (36.5%). Analyses of the 24-year period using three methods (by 6-year intervals, decades of 1980s vs. 1990s and early vs. late 1990s) provided no evidence of an increasing trend of juvenile (under age 18 years) involvement in the killing of parents. The clear lack of evidence for an increase in the killings of mothers and fathers by juveniles in the 1980s and 1990s seems at odds with the increased reporting of parricidal incidents by the media since the early 1980s.

PATHWAYS TO PREVENTION

Developmental prevention involves intervening early before crime or serious behavioral problems

emerge or become entrenched, modifying social arrangements through the organized provision of resources to individuals, families, schools, or communities. Persuasive scientific evidence suggests that this approach works, based primarily on a range of studies that commenced in the United States before the 1980s, such as the Perry Preschool Project (enriched preschool for disadvantaged children) and the Elmira Prenatal/Early Infancy Project (nurse home visiting to support pregnant, single teenage women). Pathways to Prevention is a program of research on developmental prevention that began in 1997 with work by the Developmental Crime Prevention Consortium that reviewed the international evidence on the effectiveness of this approach and assessed its policy implications for Australia.

The consortium identified a huge range of creative initiatives that collectively held great promise, but they found that relatively few of these initiatives were well evaluated. They concluded that it was time to invest in one or more demonstration projects to develop a local body of scientific knowledge about how to execute developmental prevention systematically in Australian conditions, especially in disadvantaged communities where needs are most concentrated. The Pathways to Prevention Project (Pathways) in Brisbane is implementing these recommendations in one of the most disadvantaged urban areas of Queensland, based on a strong foundation of ongoing research.

Aims and Methods

In broad terms, the Pathways Project aims to increase opportunities for people from disadvantaged groups, improve their well-being, and gain access to societal resources, thus promoting *social inclusion*. These aims are achieved by strengthening developmental systems through the provision of resources in a holistic fashion early in developmental pathways, before problems emerge or become entrenched.

The Pathways Project was developed in 2001 as a partnership between Griffith University, national community agency Mission Australia, and the Queensland Department of Education. Based on developmental systems theory, the project operates on the basis that children's well-being relies on the

success with which several organizations and social settings (e.g., families, schools, communities, and social service agencies) work together. The project philosophy is a synthesis of *community-centered approaches*, which emphasize community embeddedness, practitioner insights, and the improvement of existing practices, with *research-to-practice models* that emphasize an independent body of high-quality scientific evidence that is implemented with high fidelity by complaint practitioners. Several key features of the project design are as follows:

1. A focus on measurable improvements in children's well-being, including antisocial behaviors and social skills
2. An integrated developmental/ecological approach that reduces risk factors and promotes protective factors at multiple levels
3. An emphasis on building relations or connections between the multiple levels of organization in the developmental system, especially among children, families, schools, and community agencies
4. The simultaneous incorporation of programs at the level of the child, parent and family, school, and community (particularly the major ethnic communities)
5. A focus on key life transitions, such as the start of school
6. A community development framework that promotes family and community empowerment and the creation of more child-friendly institutions and community settings
7. Methods that facilitate an understanding of community needs and the processes through which change has been effected through Pathways
8. A commitment to measuring costs and assessing cost-effectiveness

The Mission Australia Pathways Family Support team consists of 17 community and professional staff, with most of the community workers drawn from the Vietnamese, Pacific Islander, and Indigenous communities. In addition, a teacher is seconded full time to the project. The University team consists of four researchers and two doctoral scholars.

Participants and Outcomes

In mid-2008, 3,757 children were in the Pathways database, 2,072 of whom were enrolled in one of seven participating primary schools. Four hundred and forty-one children were involved directly or indirectly through their families in the family support program (21.3% of enrolled children). In all, 599 families were entered into the Pathways database of participants.

Participation in Pathways has been shown to be associated with a range of positive outcomes, which include reduced levels of difficult child behavior; increased preschool language skills; improved grade 1 school performance; higher ratings of school readiness; higher levels of involvement in children's learning, reduced isolation among participating families, and better links to support services; greater confidence in parenting role among participants of family-based programs; greater involvement of parents in the school; and a growing perception by schools of Pathways community workers as key contributors in the school and their cultural communities. An economic analysis also shows that Pathways is cost-effective in comparison with Education Department remedial programs.

Achievements and Impact

Pathways is a model of practice in disadvantaged areas that is research-based and practice-informed; flexible, comprehensive, and persevering; effective; cost-effective; sustainable; replicable; and can be brought to scale.

Pathways shared first prize in the 2004 National Crime and Violence Prevention Awards, and in April 2004, the Prime Minister announced a new multi-million-dollar program, Communities for Children, which is strongly influenced by the learnings from Pathways. Pathways has also had a major influence in Australia on policies in such diverse fields as mental health, substance abuse, juvenile crime, child protection, and special education.

PEACEMAKING: ALTERNATIVE COURT REMEDIES

Peacemaking, in both criminological theory and criminal justice practice, emphasizes adjusting relationships, resolving conflicts, cooperation, and rehabilitation. The peace perspective is an inclusive policy model designed to empower all participants and provide them with an opportunity to change their behavior and manage their future. In practice, Navajo peacemaking courts demonstrate the utility of the peacemaking process as an alternative to the punitive construction of traditional criminal courts.

Peacemaking Courts

The Court

The Navajo peacemaking court formally emerged in 1982 as a synthesis of traditional

Native American dispute resolution and Western court methods. Peacemaking courts are leading examples of restorative justice seeking something more effective than retribution and punishment. However, Navajo peacemaking is distinct from the Western restorative justice practice of mediation.

Navajo peacemaking is unique because it foregoes the goal of identifying and punishing wrongdoers to teach them a lesson. No sense of guilt or innocence is felt in peacemaking. Guilt, which implies a moral fault and demands punishment, is a nonsensical word in the Navajo language. Peacemaking is more concerned with the healing of the victim and the community through adjusting relationships than it is with punishing an offender. Inclusion is the key to peacemaking; disputants, their blood relatives, and persons with clan affiliation are all invited to participate. Every dispute process is individualized.

Navajo peacemaking courts are used for a variety of offenses, most of which are misdemeanors such as driving while intoxicated, assaults, batteries, and public order crimes, such as disorderly conduct. The court also handles cases of intimate partner violence as well as orders of protection. Alcohol use and familial violence is common among peacekeeping court cases.

In peacemaking courts, there are no formal rules of procedure and no display of evidence; even finding the “truth” is recognized as irrelevant. The focus of peacemaking is to fix an underlying problem of which each dispute is only a symptom. All parties are guided to move from the head to the heart to achieve the final goal of reconciliation. Although peacemaking is not formalized, the three general phases to the peacemaking process are talking things out, lecture, and reconciliation.

The Court Philosophy

Peacemaking courts do not adhere to the traditional “vertical” structure of power and control. The vertical system of justice relies on a line, on the hierarchy of power made up by judges, juries, lawyers, and other court participants. Whereas case participants occupy a position at the bottom of the authority hierarchy, they are required to abide by a decision handed down from the top. Advocates of peacemaking submit that the traditional vertical system of justice is so concerned with winning and losing that when parties come to the end of the

case, little or nothing is done to solve the underlying problems that caused the dispute in the first place. Although vertical justice, through adversarial law and adjudication, offers win-lose solutions, Navajo justice is intended to provide a win-win solution.

A circle is often used to illustrate the concept of Navajo justice. It is perfect, unbroken, and represents unity and oneness. Every point (or person) on the line of a circle looks to the same center as the focus. In a circle, there is no first or last, no top or bottom, and no beginning or end. In a circle, as in peacemaking, every person and every opinion is of equal importance.

Navajo peacemaking is rooted in traditional values and opinions about the world and the human's role in the world. First, Navajos believe humans are neither an animal nor a god. Second, tradition describes humans as innately good. As a result, when someone hurts another person, there is a conflict between the bad act and the offender's human goodness. A coping mechanism is needed to deal with the conflicting states; this coping mechanism is referred to as cognitive dissonance.

Cognitive dissonance, or the mental mechanism in which all humans deal with conflict, is recognized as an important part of the peacemaking process. Peacemakers believe that individuals cope by rationalizing their behavior to themselves and others through excuses and explanations. The excuses may include denial, minimizing of the behavior, or externalization (victim blaming). Denial is one of the most frequent excuses offered by offenders in peacemaking and Western courts alike. However, in Western courts, even those who plead guilty may not offer cause for their behavior when prompted by the court. When minimalization is used, it often exploits stereotypes of age or gender, for example, that "boys will be boys." Externalization also uses stereotypes; it was the woman's fault that she was beaten or raped, that men "just can't help themselves," or that "she was asking for it."

In addition to offender-precipitated excuses, cognitive dissonance can appear in other forms such as pure ignorance of the harm caused by offending behavior, a disconnect of values or morals, or simply acting out because of underlying social or psychological problems. Another reaction to cognitive dissonance is shame. Peacemaking

views shame as the root of all violence, as the violence is an attempt to replace the feelings of shame with feelings of pride.

The Peacemaker

The person who presides over the peacemaking process is not a neutral party in the sense of a mediator. Instead, peacemakers, or *naat'aanii*, are community leaders who hold a position of respect within the community. Peacemakers should exert the qualities of integrity, honesty, and humanity and have the ability to resolve local problems. There are no leaders or followers in the peacemaking process, so peacemakers are recognized as guides to the process of healing, integration with the group, and the end goal of restoring relationships for the all participants.

Phases of the Peacekeeping Process

Navajos view peacemaking as a ceremony with prayer as a central part of the practice. Prayer summons supernatural beings to the peacemaking process and helps participants focus and commit to a positive outcome. Prayer prepares participants for the first stage of the peacemaking process, the talking things out, and it encourages them to enter into peacemaking sincerely with an open heart and mind.

Talking Things Out

Talking things out is the first phase of the peacemaking process. The talking things out phase also allows for all the participants to expose excuses for behavior and respond to them as well as to reflect on their own behavior, to visualize its impact on others, and to make necessary adjustments. Because equality is the foundation of the peacemaking process, everyone contributes to the process of talking things out and is encouraged to express opinions about both the facts and the outcome of the dispute. The presence of family and friends is an assurance that the weak will not be abused, the silent and passive will be heard, and those who are in denial about their behavior are forced to recognize the truth.

The peacemaking process recognizes that offenders use excuses such as drunkenness, stress, or victim blaming to justify their behavior. The

peacemaking process creates an environment for offenders to work through those excuses. During the talking things out phase, the victim will explain the offense from their own point of view and express how the offender's behavior made them feel. After the victim's recount of the event, the offender then gives their point of view. It is at this point that they may begin to list their excuses, because the offender believes the excuses and has internalized them as reality. However, the offender's family and friends are present during the peacemaking process and will confront the offender about the excuses. This confrontation can be a powerful step in the healing process because the message is coming from those closest to the offender and not a stranger, such as a judge or social service provider. In addition to overcoming excuses, the talking things out process also helps break down emotional barriers held by participants that may prevent them from viewing the situation clearly.

Because peacemaking is inclusive, the process takes into account the participants' shared values and attitudes. These same values become norms that represent the foundation of the law itself. Unique to the peacemaking process, authority is given to participants to choose the most appropriate law for their situation. There is no formal debate regarding the philosophy or principle of law, but instead there is a discussion about how best to resolve the problem at hand.

The Lecture

The next phase of peacemaking is the lecture, a form of teaching by the naat'aanii. During the lecture, the peacemaker taps into Navajo traditions and draws parallels between the dispute at hand and a problem from the Navajo creation times. Peacemakers talk specifically about how the historic issue was resolved and how that resolution can be applied to the current dispute. Participants are then encouraged to exercise empathy as offenders learn the inadequacies of their excuses and attempt to adjust their behavior for the future.

The Reconciliation

The last stage of the peacemaking process is the reconciliation. During this phase, all participants

must come to an agreement about what should be done to resolve the dispute. First, there must be a consensus about the relationships and about where participants stand with each other at the end of the peacemaking process. Only when the relationships are healed can consensus be reached about restitution or reparation to a victim. The reconciliation can result in anything from an exchange of material goods or money; a commitment from the family to watch over the offender or make sure certain promises are kept; or a commitment of the offender to Western therapy or counseling. The key to the reconciliation is the lack of force or coercion. It is a consensus not a command. The key to the success of peacemaking is the balance between personal autonomy and the greater good of the community. Peacemaking's focus on problem solving not problem blaming is conducive to all participants to communicate and reach a productive conclusion.

PEACEMAKING/ SENTENCING CIRCLES

A sentencing circle—sometimes called a peacemaking circle—is a community-directed sentencing/peacemaking process (as opposed to a conventional state-directed criminal justice proceeding), which aims to address offending behavior and establish community safety through drawing on the wisdom, experience, and capacity

of the community. Although distinct to state-based justice, this community-based process works in partnership with juvenile and criminal justice professionals and systems. The circle process often involves the victim, victim supporters, the offender, offender supporters, judge and court personnel, prosecutor, defense counsel, police, and all interested community members. Whereas state-based justice proceedings focus on guilt and punishment, circle processes focus on responsibility and healing. As such, circle processes require the offender, and others, to take responsibility for their actions, and for the community to have the capacity to be involved in a healing process. As the community becomes more involved in the justice process, the convening of a sentencing circle, along with the adoption of the community sentencing plan, are generally at the discretion of a judge.

The aim of a sentencing circle is for all parties to develop consensus on an appropriate sentencing (or peace) plan that addresses the concerns of all parties (community and state). Sentencing and peacemaking circles are a form of restorative justice, which has been defined as a process in which everyone who has an interest in the offense works together to address the impact of the action on all parties involved. Although this is not the only definition of restorative justice, this process-based definition has been widely adopted (e.g., by the United Nations).

The sentencing (or peace) process is convened in the form of a circle of participants, hence the name, which creates a dialog space in which all participants (state and community) can work with one another as equals within a system of mutual interdependence to build collective understanding and resolve. Together, the participants identify what steps are necessary to address the needs of all community members, including the offender(s) and the victim(s). The broad aim is to establish individual and community capacity to repair the harm done and to prevent more harm.

Sentencing circles often involve a multistep procedure that includes (1) application by the offender to participate in the circle process, (2) healing circles for the victim, (3) healing circles for the offender, (4) a sentencing circle to develop consensus on the elements of a sentencing plan, and (5) follow-up circles to monitor the progress of the offender. The sentencing plan may incorporate

commitments by the system, community, and family members, as well as by the offender. Sentencing circles are used for adult and juvenile offenders across a variety of offenses, and they have been used in both rural and urban settings. Specifics of the circle process vary from community to community and are designed locally to fit community needs and culture.

Although circles have been used in many ways (sentencing, peacemaking, healing, etc.), the common aim is to develop an atmosphere of respect and concern for everyone, building on the tradition of talking (or dialog) circles, which is common among indigenous people of North America. A talking piece, passed consecutively around the circle from person to person, regulates the dialog. The person holding the talking piece has the undivided attention of everyone else in the circle and can speak without interruption. The use of the talking piece allows for full expression of emotions, deeper listening, thoughtful reflection, and an unrushed pace. Additionally, the talking piece creates space for people who find it difficult to speak in a group. Drawing on both traditional wisdom and contemporary knowledge, a sentencing circle also incorporates elements of modern consensus-building processes.

Circles aim to promote healing for all affected parties; provide an opportunity for the offender to make amends; empower victims, community members, families, and offenders by giving them a voice and a shared responsibility in finding constructive resolutions; address the underlying causes of criminal behavior; build a sense of community and its capacity for resolving conflict; and promote and share community values.

A successful sentencing circle process depends on a healthy partnership between the formal justice system and the community. Participants from both backgrounds need training and skill building in the circle process, peacemaking, and consensus building. The community often customizes the circle process to fit local resources and culture.

History and Growth

In Canada, the harsh realities of the justice system on Aboriginal people began to be more fully recognized in the late 1980s and early 1990s, with disproportional representation and high recidivism

and crime rates being widely recognized. This was particularly true in Canada's Northern Territories and Prairie Provinces. Recognizing that a shift in judicial practice needed to take place, Judge Barry Stuart, of the Yukon Territorial Court, adjourned the case of *R. v. Moses* (who pled guilty to carrying a baseball bat with the intention of assaulting a police officer) and convened the first sentencing circle, drawing on the wisdom of traditional Aboriginal practice in the Yukon Territory. This wisdom is based on the following three guiding premises: (1) a criminal offense represents a breach of the relationship between the offender and the victim/community, (2) the well-being of the community is dependent on healing these breaches, and (3) the community is the best resource to address these breaches. In Canada, sentencing circles have been developed most extensively in the Prairie Provinces of Saskatchewan, Manitoba, and the Yukon. The use of sentencing circles spread to the United States in 1996 when a pilot project was initiated in Mille Lacs in central Minnesota, and to New South Wales, Australia, where a pilot program was conducted in Nowra in 2002.

Evaluation and Evidence

The most rigorous evaluations to date of sentencing circles has been conducted in New South Wales, Australia, where a pilot program in Nowra began in February 2002. In the first 12 months of the program's operation, the study examined 13 offender participants (11 male and 2 female) and 8 cases. Surveys were completed by defense solicitors, police, prosecutors, the magistrate, defendants, and victims. The evaluation supported the effectiveness of sentencing circles, noting that this alternative justice process was effective in reducing barriers between the courts and Aboriginal people, raising the level of support for Aboriginal people, incorporating victim support, empowering the Aboriginal community, offering relevant sentencing options with community support, and reducing recidivism. The only deficit noted was the significant time commitment required to process an offender through a sentencing circle. The report recommended that sentencing circles be expanded to other regions of the state, where Aboriginal communities reside. Based on this recommendation, other programs began to operate in Armidale,

Bourke, Brewarrina, Dubbo, Kempsey, Lismore, and Mt. Druitt. Legislation was also passed amending criminal procedure for sentencing circles in 2003, whereby once an offender has pled or been found guilty, he or she must pass a suitability test by the court and an acceptability test by the Aboriginal Community Justice Group (ACJG). The ACJG will consider the nature of the offense and its impact on the community, whether the offender has strong links with the community and the potential benefits of the circle to the offender, victim, and community. In 2005, the following eight objects of sentencing circles were set out in the NSW Criminal Procedure Regulation: (1) to include members of Aboriginal communities in the sentencing process, (2) to increase the confidence of Aboriginal communities in the sentencing process, (3) to reduce barriers between Aboriginal communities and the courts, (4) to provide more appropriate sentencing options for Aboriginal offenders, (5) to provide effective support to victims of offenses by Aboriginal offenders, (6) to provide greater participation of Aboriginal offenders and their victims in the sentencing process, (7) to increase the awareness of Aboriginal offenders of the consequences of their offenses on their victims and the Aboriginal communities to which they belong, and (8) to reduce recidivism in Aboriginal communities.

A rigorous evaluation of the recidivism objective was commissioned in 2006, examining the following three aspects of recidivism (within a 15-month period): reduction in frequency, time to re-offend, and reduction in seriousness of offending. Compared with the court-processed control group, this study suggested that circle sentencing has no effect on any of these recidivism outcomes. As such, this more rigorous study does not replicate the finding of the pilot study, which did report a reduction in recidivism. However, as this second study concludes, this finding should not be generalized to conclude that circle sentencing has no value simply because, at this time, it seems that the process has no short-term impact on reoffending. This study did not examine the impact of any other objectives the sentencing circle set out to examine. For example, if the process strengthens the informal social controls in the communities served by sentencing circles, then the process may have a crime-prevention value that cannot be

quantified in studies of reoffending. It also may be the case that other objectives, such as increasing the confidence of Aboriginal communities in the sentencing process, must be first realized before the reoffending objective is realized. Beyond the justice system, other systemic influences (e.g., family, peer groups, and alcohol and drug programs) may also need to be addressed through integrated community-support mechanisms.

Sentencing Circles and Indigenous Jurisprudence

Although the evolution of circle sentencing/peace-making has a distinctive developmental history, there are certain elements that dovetail with other indigenous justice developments. For example, the village of Hollow Water in Canada began a Community Holistic Circle Healing (CHCH) program in 1984, in response to concerns about levels of substance abuse, vandalism, truancy, suicide, and violence, and over time it came to focus on the hidden problem of family violence and sexual abuse. This community-based program works in partnership with the court system, where a community-based sentence is often imposed in conjunction with a suspended incarceration sentence, which is enforced in cases of violation of the community-based sentence. In the first 10 years of the CHCH program, only 4 of 48 offenders had been re-incarcerated for sexual abuse.

In the United States, Chief Justice Robert Yazzie of the Navajo Nation states that the Navajo courts first came into being in 1959, with the 1985 Judicial Reform Act paving the way for the additional development of the Navajo Peacemaker Program. Unlike sentencing circles, lawyers, judges, and legal support services do not take part in the peacemaking process. The process is convened by the Peacemakers and the community. Several key elements make the process distinctive in other ways: Peacemakers are not impartial; Peacemakers take direction from traditional Navajo wisdom narratives; the emphasis is on relational/communal healing, not individual healing; evidence is secondary and feelings are primary to the process; and objectives align with traditional Navajo wisdom.

In Australia, every state (bar Tasmania) now has some form of Indigenous sentencing court, each with their own defining characteristic. Most

of these are based on the Nunga Courts of South Australia, which first developed in 1999 and are more aligned with conventional court proceedings, wherein participation of Elders, community, and victims is not as strong. The Northern Territory Community Courts are a hybrid of the Nunga and the sentencing circle models. Only programs in New South Wales and the Australian Capital Territory are based on the sentencing circle process that originated in Canada.

These developments have lead many to argue that the development and use of sentencing/peace-making circles needs to get beyond the focus on recidivism and incarceration rates, to a focus on the politics and governance of intergroup relations and social change.

PEDOPHILIA

Pedophilia—sexual perversion targeting children—has been a topic that has galvanized the attention of the public for several years. In contemporary Western society, those who participate in this deviant form of sexual interplay have been labeled as the worst and most vile criminals. However, historically, those who engaged in sexual relations with children were not viewed as the villains that they are today. For instance, in ancient Roman society, it was normal for an adult male to take on a child as a sexual concubine. In fact, not only was

it considered the highest form of love, but also there was intense competition to get one's child "hooked up" with the right person who could not only teach the child the ways of the world but also teach him a skill or trade that would become his future career.

Today, the situation is different. In contemporary society, the pedophile is recognized as a perverse sexual offender who targets and victimizes innocent children for his own sexual gratification, often causing long-term damage to his victim's psyche. This entry first defines pedophilia and then discusses types of pedophiles, the etiology of pedophilia, and the incidence and prevalence of pedophilia. Last, this entry briefly discusses how to stop this threat to children.

Definition

Pedophilia by definition is a psychological disorder experienced when an individual has recurrent, intense sexual urges or sexually arousing fantasies of engaging or repeatedly engaging in sexual activity with a child. It is currently listed as a diagnosable disorder in the *Diagnostic and Statistical Manual of Mental Disorders* (4th ed.). To be found to have pedophilia, a person must exhibit the following criteria:

- a) Over a period of at least 6 months, recurrent, intense sexual arousing fantasies, sexual urges, or behaviors involving sexual activity with a prepubescent child or children (generally 13 years of age or under)
- b) The person has acted on these sexual urges, or the sexual urges or fantasies caused marked distress or interpersonal difficulty
- c) The person is at least 16 years and at least 5 years older than the child or children (p. 572)

A person who suffers from pedophilia is different than many other sexual predators in that the person often specializes in the age of his or her ideal victims and usually does not involve violence in the commission of his or her acts.

Despite the definition, many people often confuse pedophilia with other types of sexual molestation of children by adults. For this reason, it is important to denote the many different types of

child molesters usually discussed under the umbrella of child molestation.

Types of Pedophiles

When one speaks of pedophiles, two primary distinctions come to mind. The first distinction that is commonly made is the ideal victim type of the offender. If the offender prefers children under the age of adolescence, the offender is commonly referred to as a pedophile. If the offender has a sexual preference for children after the onset of puberty, the offender is often referred to as hebephile. This distinction is important because it not only denotes the interest of the offender but also often tells much about the offender, his or her activities, and how he or she courts victims.

Pedophiles and Hebephiles

In general, pedophiles often prey on victims that come from a family in crisis or one in which the offender can develop a close relationship to the victim. Pedophiles may work in the schools or volunteer their time in places where children congregate. A level of trust is developed during the course of time based usually on a common interest. Most pedophiles do not wish to harm the child but wish to share something special with their child of choice. The victim may crave an adult's attention or simply participate in the relationship to acquire tangible objects that he or she desires (e.g., toys, games, etc.). In most cases, the offender will not force sexual intercourse on the victim but instead will ask the victim if he or she can touch or hug them before actually engaging in a sexual embrace or activity.

Similar to pedophiles, hebephiles often prey on children from a family in crisis. Sometimes, they develop a close relationship with their victims, and sometimes they do not. In most cases, the relationship that develops is one based on a "commodity-exchange" relationship. Usually, the hebephile has something that the victim wants, and the adolescent will play along to get that commodity. Most often, these commodities include items that are attractive to teens, including but not limited to sports equipment, video games, alcohol, drugs, or concert tickets. Most hebephiles do not commit their offenses without asking for permission. Even

though several similarities are observed between these two offender types, it is important to note that rarely will a pedophile molest a child after the age of adolescence and vice versa. Pedophiles generally will lose their sexual interest in a child after the child goes through puberty. Thus, the pedophile will often discard the child and begin searching for a new victim, one who matches his or her ideal victim type.

Pedophiles and Incest Offenders

Another key distinction in understanding pedophiles is the relationship between the child and the offender. Many people confuse the pedophile and incest offender because both often use the child for their own sexual gratification. Although both types of offenders cause a significant amount of harm (either psychological or psychical) to the child, the incest offender is often the most dangerous because the child has no one with whom he or she can discuss the event. It is difficult for a child to admit that he or she was sexually abused; confiding in someone means that a family member may go to jail, parents may get a divorce, or family members may not believe the child, which places the child in an untenable position. Despite these factors, pedophiles are often referred to as those who fall outside the family. Incest offenders often molest children and cause damage to their victims that is qualitatively different than that of pedophiles.

Types of Child Sexual Offenders

Whereas it is important to distinguish between these two groups, not all pedophiles or hebephiles are alike. Stephen Holmes and Ronald Holmes offer a typology of those offenders who prey on children. They claim that four types of pedophiles exist, which include the immature, regressed, sadistic, and fixated offenders.

Immature Child Offenders

This type of offender does not understand the true nature of his or her offenses or the societal rules that prohibit the involvement of adults with children in a sexual manner. Some suffer from organic problems or senility and cannot appreciate the impact of what they have done; for example, the elderly grandfather or the older gentleman who

lives down the street may suffer from impaired intellectual functioning and may not understand the ramifications of his actions. This offender likes to hug, fondle, kiss, lick, or stroke a child, with no intent to attempt sexual intercourse or sexually molest the child.

Regressed Child Offender

The regressed offender is one who has historically been involved with adults in “normal” sexual relationships. Psychologically, this type of child offender experiences the child as a pseudo-adult. Typically married or in a long-standing relationship, this sex offender is often launched into a sexual act or series of sexual acts with children because of some precipitating event. This offender prefers children he or she does not know. Usually, the child is a female but this is not always the case.

Compared with other sexual child offenders, the regressed child offender has the best chance of not reoffending, especially if precipitating event or cause can be discovered and remedied.

Fixated Child Offender

This child offender has not really developed past the point where he or she, as a child, found children attractive and desirable. In other words, they have become “fixated” at an early stage of psychosexual development. The pedophilic interest of the fixated type of child molester generally begins in adolescence.

The fixated offender has little activity with age mates, is single, and is considered to be immature and uncomfortable around adults. This offender is as a child in his lifestyle and behaviors. The fixated child offender loves children and does not desire to do anything that might harm them. They court them, buy them gifts as a seduction ploy, and slowly become physical. Oral-genital sex is the norm, and actual intercourse develops only after a generous period of time has passed.

Sadistic Child Offender

Some child sexual offenders are intent on molesting children with the express desire to harm their victims physically. This type of pedophile, usually male, has made a vital connection between sexual arousal and fatal violence. Typically, the child is a stranger to this aggressive and sadistic child offender.

The sadistic offender will often abduct a child from places where children gather, such as playgrounds, school, shopping center game rooms, and other such places. Usually, he will not attempt to seduce or otherwise induce the child to go with him; he simply takes the child by force.

Often, the sadistic offender will mutilate the body of the child or commit acts of necrophilia. The sadistic child offender will often terrorize the child because he lives to feed off the terror of his victim. Sometimes a weapon is used, and the crime is both premeditated and ritualized. Sadism is an integral part of the sadistic offender's predation.

Etiology of the Pedophile

The basic etiology of the pedophile is currently unknown. What is known is that pedophiles and other child molesters are generally men. They generally match the U.S. population in terms of education, marital status, and religious observance practices. Furthermore, it is now believed that the pedophile often begins the offending behavior at a young age, most often before the age of 20 years.

Anna Salter suggests that several predisposing factors may lead one to molest children. These factors include deviant arousal patterns or the molestation itself provides the offender a way to medicate for other nonsexual problems. Most pedophiles come from homes with domineering mothers or passive/absent fathers. Furthermore, most child abusers suffer from low self-esteem and poor coping skills.

Pedophiles and hebephiles also generally have minor or no criminal records. Thus, when their crimes are first brought to the attention of the police, there are no records on them. In many ways, they are thought to be offense specialists. That is, they only commit one type of crime, which is generally sexual in nature.

Incidence and Prevalence

National statistics reveal that roughly 25% to 33% of all young girls will be sexually abused prior to their 18th birthday. Similarly, slightly less than 20% of all boys in the same age range will be a victim of some type of sexual abuse by the time they finish high school. Just how many of these children are victims of a child sexual abuser is difficult to ascertain because we do not have good

official statistics. Furthermore, it is estimated that less than 10% of victims will report their crime.

What is known is that boys report the crime far less often than girls and that molesters of girls report an average of 50 victims before being arrested. The number of victims for those who prey on young boys is much higher. It is estimated that these offenders victimize an average of 150 young men before being arrested.

Gene Abel and Nora Harlow claim that offenders who molest children before the age of adolescence victimize as many as four times the number of victims that hebephiles do. In their study, they found that the average pedophile molested 11.7 more children than the average hebephile. The offenders who prey on older children molested 2.9 children on average. When it comes to the number of sexual acts, they found that those who prey on younger victims (pedophiles) commit an average of 71 molestations events compared with 6.5 acts for those who prey on older children or adolescents (hebephiles).

The sexual interest and molestation of children is more prevalent than one would like to think. In terms of interest, Brier found that in a sample of 193 male undergraduate students, 21% reported a sexual attraction to children, 9% described fantasies involving children, 5% admitted to masturbating to these fantasies, and 7% indicated a likelihood of having sex with a child if they could avoid punishment and detection.

Stopping the Threat

Pedophiles and other forms of child sexual offenders represent a real threat to children. Although many do not recognize or understand the harm they are doing, the extant research shows that many who have been sexually abused as a child grow up with deep psychological scars that stem from the abuse. Parents, teachers, and others in positions of authority must share in the educational campaign to let children know that the sexual abuse and exploitation of minors is not appropriate, cannot be tolerated, and should be reported immediately. It is only through open communication between children and their caregivers do we have a chance at catching and stopping these offenders.

PEER COUNSELING

Peer counseling can be defined as a method of helping that uses the sharing of information, feelings, and expectations of individuals who have experienced a similar situation or who may be more likely to empathize with an individual because of similarities in chronological age. Often, peer counselors are not professional counselors, but their expertise lie within the common experiences shared between two or more individuals. Peer counseling may sometimes be referred to as *peer helping* and can be conducted individually or within groups. One-on-one peer counseling is usually used in educational or mentorship programs, whereas group peer counseling is often used in rehabilitative intervention and prevention programs. When referring to peer counseling where victims of crime are concerned, individual and group peer counseling can be most effective and important tools for healing. However, peer group influence with perpetrators of crime may be less successful.

Background

The first Peer Counseling program was started by Barbara Varenhorst in the Palo Alto, California, school district in 1970. The importance and usefulness of peer helping behavior evolved out of the developmental research on peer relationships. Several aspects of the impact peers, such as peer socialization, peer friendships, and peer pressure, are considered important to development. *Peer socialization* is a term used to identify how peers tend to learn from one another. Individuals who are around peers of the same chronological age can gain important information about themselves, such as understanding how they are viewed by others, whether their ideas and opinions are valued, and appropriate and inappropriate emotional and behavioral responses. *Peer friendships* serve to deepen the quality and degree of closeness in relationships. Peer friendships are usually developed based on similar interests, hobbies, and common goals individuals may have with one another. These friendships often serve to make the socialization process more meaningful for peers. The connection that peers make may lead to either positive or negative relationships. For example, a positive relationship can add value to the individual's self-concept, whereas a negative relationship can cause conflict and aversive consequences for individuals. Negative peer pressure can lead to problem behavior and friendships. *Peer pressure* occurs when an individual feels stress and is (usually mentally) pushed to conform to a behavior or idea of others. This can occur after a single contact situation or prolonged interaction between two individuals or within a group. A person may give in to peer pressure and conform when they feel insecure in social relationships. This often occurs in adolescence or early adulthood, although it can happen at any time during development within young children into adulthood.

Erik Erikson's theory of psychosocial development describes adolescence as period of growth in which peer relationships are highly influenced by the identity and self-development. According to Erikson, the adolescent period is one of identity confusion and identity role development. Peers play a strong role in the development of discovering important aspects of self during adolescence and early adulthood. During this stage, peer relationship

influence can become even stronger than parental influence for some individuals.

Peer counseling skills evolved out of the ideas of Carl Rogers, whose input in the field of counseling had a tremendous impact on the importance of developing the helping relationship. He emphasized the essential need to provide warmth, genuineness, and active listening skills in counseling sessions.

Peer Counseling as Intervention and Prevention

Peer counseling programs have been instituted in the schools on all levels from elementary to colleges and universities. On the elementary and secondary levels, peer counseling may range from less structured helping in the classroom with academic work to more structured peer-mediation programs. When conflicts occur in the schools, it may be more beneficial to have trained peers to help mediate and negotiate a solution. Peer mediation programs can be beneficial to the schools, parents, and students in terms of decreasing suspensions and detentions. Colleges and universities use peer counseling and mentoring, student orientation programs, and prevention programs such as the prevention of alcohol abuse, sexual harassment, and so on.

Other community programs that focus on behavioral intervention have reports of mixed outcome. Although peer influence is mostly effective, it can be detrimental depending on the context within which it is used and presented. Much of the research on peer influence has focused on assessing its impact on delinquent individuals within adolescent groups. It is mostly agreed that within a group of adolescent peers, if one person presents a problem or negative behavior, it is highly likely that other members of that group may do the same. So, employing peer counseling for such a group in which the counselor is similar in age and also has a delinquent background may not be successful. It may be more advantageous to use nondelinquent peers as counselors and role models. It should be noted that negative and delinquent behavior is not necessarily caused by peer influence. Most research notes that negative peer influence is more likely when a group lacks structure and has limited defined boundaries.

It has also been shown that training peer counselors can yield positive results. It can help the peer

counselor become aware of and enhance his or her own skills and talents. It may also help the peer counselors develop competent social skills and self-esteem. This advantage of peer counseling may be the most powerful prevention of negative and criminal patterns of behavior.

PEER MEDIATION

Mediation is defined as a structured method of conflict resolution in which trained individuals, called mediators (impartial third parties), assist people in dispute (the parties) by listening, facilitating communication, and promoting voluntary decision making by the parties in dispute. Peer mediation grew out of the wider mediation movement, with the trained mediator being a fellow student (or students). These students support other students in taking responsibility for resolving conflicts and disputes, typically as part of a broader youth empowerment and school safety strategy.

This strategy typically involves peer mediators receiving 12 to 20 hours of training about interpersonal conflict, communication (e.g., active listening, paraphrasing, and reframing), mediation (e.g., ground rules and role plays), program policy, and procedures. The broad aim is for this structured peer-led process to become part of the ethos of the school, through disputants actively participating in decisions about issues and problems that are central to their own well-being.

Peer mediation programs grew rapidly in the mid-1990s in response to rising incidents of violence in schools. Early evidence suggested that the programs were effective for several reasons, which include the following: discipline is less time consuming for teachers; family relationships, particularly among siblings, are improved through developing communication and conflict resolutions skills; a safe place for children to learn about conflict resolution is created; schools that are proactive about conflict resolution usually have a more cooperative climate on the whole; and students learn about rights, responsibilities, and consequences, as well as choices.

For example, a 1998 study by Alison Soutter and Anne McKenzie of peer mediation programs in New South Wales, Australia, found that 15 schools involved in a peer mediation program, compared with a control group, reported a lower incidence of reported fighting, lower incidence of students believing that avoiding the person/problem was a good way to resolve disputes, lower incidence of disputes being resolved through a disciplinary warning, higher incidence of teacher discussing disputes with affected parties, and higher incidence of students talking with teachers/counselors. The schools in the control group reported increases in suspensions, number of students being sent to the executive by their teachers, belief that disputes could not be resolved through discussion, belief that disputes could be resolved through fighting/arguing, and belief that avoiding the person/problem was a good way to resolve disputes.

As a result of this early evidence, peer mediation programs became a widespread means of peers resolving conflict in schools. Now, thousands of programs are in existence, grounded in a wide variety of mediation models. This proliferation led to the early systematic reviews of peer mediation programs, which generally showed nonsignificant or

weak effects overall. In light of this evidence, many researchers and practitioners argued that peer mediation alone was not a strong enough intervention to shift the overall climate of the school, particularly for chronic problems and serious incidents.

In response to these findings, New South Wales, for example, developed and launched a more intensive program to complement peer mediation and reduce the number and length of suspensions in schools. The aim of this intensive and collaborative decision-making program was to engage students at risk in a supportive network where they could learn from their experiences in school. This collaborative decision-making process was based on a form of restorative justice, which was facilitated by an impartial third party and included a broader range of participants than the disputants. It was found that a continuum of congruent practice was more efficient in changing the school culture. Other school districts chose to support peer mediation programs through more proactive universal programs that built the skill base of all students, beyond the mediators. For example, an evaluation of the Resolving Conflicts Creatively Program found that schools which strengthened universal programming, while maintaining their peer mediation, were more effective in managing behavior in comparison with schools that emphasized peer mediation more than universal programming.

Within the past 5 years, meta-analytic reviews of peer mediation programs have examined a broader range of outcome variables. For example, one study included 43 programs and coded for outcomes within the following four general headings: (1) descriptive outcomes (satisfaction and success of mediation), where an 88% satisfaction rate was found; (2) impact on the school (climate, disciplinary action, suspensions, etc.), where the data indicated a reduction in disciplinary actions after peer mediation was implemented; (3) issues related to conflict resolution (mediator's understanding of conflict and use of strategies), where results indicated that understanding of conflict did increase and consistent use of strategies were used; and (4) impact on the mediator (academic performance and self-esteem), where increases were found on both measures.

Peer mediation programs are now defined within the broad framework of conflict resolution education (CRE), and typically these programs are categorized into the following three different delivery

formats: embedded curriculum, direct skill development, and peer mediation. A recent meta-analysis of these programs examined whether CRE contributed to the reduction of antisocial behavior in K–12 schools. Of the 36 programs included in the analysis, peer mediation programs had the highest level of frequency: 17 studies, which represented 37% of students in the sample. Although the variance in magnitude underscores the complexity of the topic and the need for more rigorous evaluation, reductions in antisocial behavior were consistently observed across programs and were particularly strong for older students, which is consistent with the literature on the development of higher order cognitive ability. The evidence suggests that a whole-school approach that includes peer mediation as a vehicle that not only tackles individual incidents but also links incidents to a change program for the culture of the school is central to the success of the process.

PEER NETWORKS AND VICTIMIZATION

Peer relations have long been central to the study of crime and delinquency. This is because adolescents

spend much time with their friends, attribute great importance to friends, and are more strongly influenced by them during this period of the life course than at any other time. During adolescence, friends become primary role models for behavior and adolescents are particularly vulnerable to peer dynamics. Thus, it is not surprising that one of the most consistent and robust findings in the criminology literature is that adolescents with delinquent peers are more likely to be delinquent/criminal themselves.

Although prior research clearly establishes that adolescents are likely to behave in a manner consistent with their friends, it has only recently begun to account for the network structure of friendship relations. A network is a group of individuals who know and interact with each other. When discussing peers, members are typically connected through friendship ties and interact socially with one another. For criminologists, networks are important because they can constrain and/or direct behavior. If the friendship network is delinquent, members can influence one another to engage in delinquency by providing models for behavior, providing rewards for behavior, providing sanctions for inappropriate behavior, creating opportunities for delinquent behavior, and providing witnesses and or/protection against retaliation.

Recent Research

Drawing on this network perspective, recent research has begun to incorporate social networks into models to reveal how peer networks influence delinquent behavior. For instance, Dana Haynie's work draws on network methods to define friendship networks and finds that adolescents' risk of delinquency is increased with a greater number of delinquents in the network, when the proportion of delinquents to nondelinquents is higher, and with a higher number of delinquent acts being committed by friends. Expanding on this idea, Christopher Shreck and colleagues have demonstrated how a network approach provides a useful means of extending knowledge about how peer contexts influence victimization risks. This research is especially important as adolescence is viewed as a time of expanding vulnerabilities and opportunities that result in a widening exposure to life beyond school and family. As a result, the risks of victimization are heightened during adolescence.

Importance of Peer Networks

Why are peer networks important for assessing victimization risk in adolescence? Although some studies suggest that adolescents are motivated to join delinquent groups such as gangs for protection from victimization, other research suggests that victimization risk is increased by exposure to delinquent peers. To explain the increased risk of victimization attributed to exposure to delinquent peer networks, researchers often draw on routine activities and lifestyle theories. These theories suggest that certain activities or situations coincide with higher chances of becoming a victim, whereas other situations result in fewer opportunities for victimization. Furthermore, situations with a greater risk of victimization occur because of the proximity of a motivated offender to a poorly defended target (i.e., victim). This supports research that finds that adolescents with delinquent friends are more likely to experience victimization and indicates that association with delinquents leads to greater risks of victimization.

To explain these findings, Shreck and colleagues apply routine activity theory and posit that network structure influences one's exposure to crime, attractiveness as a target, and level of effective guardianship. This is because a delinquent peer context brings with it exposure to motivated offenders in the form of peers in the network. For instance, members of the peer network may use each other as convenient targets. Delinquent peers are likely to make less effective guardians for the benefit of other members of the group. Finally, participation in delinquency or violence as a member of the network could make an adolescent a worthwhile target for current or future victimization. This would occur if membership in a network engaging in violence invited retaliation from the group's victim. Similarly, group norms may encourage the use of violence as an acceptable means of settling within-group disputes. As these examples illustrate, exposure to delinquent/violent peer networks is more likely to increase risks of victimization than to reduce them.

In summary, research now suggests that the adolescent peer context is as important for understanding the violent victimization of adolescents as it is for explaining their participation in delinquency/crime. The approach of identifying and examining peer social networks provides a coherent and

promising framework for investigating a variety of ways that peers shape and influence adolescent behavior. This conclusion is consistent with the current emphasis on the significance of social contexts (e.g., neighborhood, school, and family) and suggests that an important context with important implications for adolescents' behaviors is the peer networks in which youth are embedded.

PERCEPTIONS OF DANGEROUS SITUATIONS SCALE

The Perceptions of Dangerous Situations Scale (PDSS) was developed to meet a need to evaluate

women's self-defense programs, but it may be useful for other venues, such as martial arts, sexual assault prevention programming, and social science research. The PDSS is based on Albert Bandura's self-efficacy theory—how confident someone feels about accomplishing a challenge is the best predictor of the person's real performance when presented with the actual task. The instrument consists of 34 crimes and dangerous situations of varying degrees of seriousness, on which women rate how fearful they are and how confident they are to manage the situation successfully. Scores can range from 1 (almost none) to 5 (almost complete). A third subscale is included in the PDSS—how likely the situation is to occur to them in the next 12 months—but it has not yet been validated. Thus far, the instrument has been administered and validated for U.S. college women only. The PDSS shows promise for investigators wanting a detailed analysis of fear of crime and for gauging confidence about managing dangerous situations.

Validation

Validation consisted of establishing content validity, construct validity, and reliability. To establish content validity, a group of 60 people knowledgeable about women, crime, or victims generated 175 situations for personal and property crimes/situations representing mild, moderate, and serious danger. A panel of seven experts from law enforcement, victims' services, self-defense, and martial arts was instructed to choose 15 representative situations for the PDSS. The developer chose the 43 items most frequently identified by the experts and asked them to answer yes/no about whether each item was representative, non-biased, appropriate, and able to differentiate between women's differing levels of fear and confidence. Two items were deleted at this stage. The author concluded the PDSS had content validity.

To establish construct validity, the author initially screened individual items with three statistical techniques to determine that they were appropriate for a principal components analysis (PCA). The author then administered the instrument to 564 university women, performed a PCA, and eliminated seven more items because of low values. Three components, or themes (subsequently identified as fear, high confidence, and low

confidence), were identified. All items were retained at this stage.

For more construct validation evidence, to determine instrument sensitivity, 135 university women completed the PDSS before and after a semester-long self-defense class. Women at the end of the semester scored significantly more confident and less fearful than they did before instruction, thereby confirming the ability of the instrument to distinguish among women before and after instruction.

In a third test of the PDSS for construct validity, the author compared PDSS scores for noninstructed women and women trained in self-defense. Again, the PDSS scores were significantly different in fear and confidence for instructed and noninstructed women. Based on the principal components analysis results and on successful tests of instrument sensitivity and known group differences, the author concluded the PDSS possessed construct validity.

Reliability for the PDSS was established through tests of stability and internal consistency. A group of 42 women completed the PDSS twice, the second time occurring 48 hours after the first administration. Fear levels were not significantly different on the two administrations, but confidence levels were higher on the second administration. The author determined that women tended to think and brainstorm about possible solutions in the intervening time frame, and thus they scored higher on the second administration.

Internal consistency was established statistically. Anything higher than .60 is recommended for scales to be used in basic research. Fear and confidence pooled and analyzed together yielded .88 (Cronbach's alpha coefficient). Fear separately was .95 and confidence alone was .94. The author determined the PDSS possessed internal consistency and stability for fear, but not confidence.

Structure of Fear and Confidence

Researchers have noted that fear of crime is a multidimensional construct—an emotional part (being scared) and a cognitive part (perceived likelihood of personally being victimized). Additionally, they have urged examination of fear in situation-specific terms, rather than generalized fear. The author subjected the PDSS to two statistical techniques (multidimensional scaling and cluster analysis) to

group fear and confidence items conceptually. All items were found to be organized in a two-dimensional matrix of personal threat (mild to severe) and intimacy (stranger to partner). Clusters of fear items seemed to be threat of death, fear of rape, auto vulnerability, theft, latent danger, dangerous drinking, stalking, and exposure to obscenities. Some confidence clusters were identical to those in fear: threat of death, stalking, dangerous drinking, exposure to obscenities, and latent danger. Unique to confidence were clusters of auto theft, threat of injury, and drugged. Although five of the eight clusters identified were common to Fear and Confidence, they did not contain identical items.

Congruent with other research, the author found that fear and confidence were distinctly separate constructs, not opposite ends of the same spectrum, and they were correlated only moderately ($r = -.41$). Fear scores tended to return to baseline after time (more than a semester but unknown how long), but confidence scores did not—they remained higher in the long-term, which indicates that confidence is a more stable construct than fear. In both studies, it was clear that women feared victimization by a stranger much more than victimization by someone known. Women reported high personal threat for situations of indirect exposure and unlikely occurrence (e.g., seeing and hearing a prowler outside), but low personal threat for situations involving common, dangerous, proximal situations (e.g., partner verbal abuse).

PERRY PRESCHOOL PROJECT

The High/Scope Perry Preschool Study found experimental evidence that a high-quality preschool program has lifetime effects on participants, cutting their crime rate in half and producing a large financial return on investment. Members of a sample of 123 young African American children living in poverty were randomly assigned to a program group that received a high-quality preschool program at ages 3 and 4 or a no-program group. Data were collected regarding them at 14 points from ages 3 through 40. The program group significantly surpassed the no-program group in tested ability and performance throughout childhood; higher adult earnings and rates of employment and home ownership; half as many lifetime arrests, including fewer for violent, property, and drug crimes; and fewer convictions and months sentenced. The economic return to society was \$16.14 per dollar invested. This article summarizes the 2005 monograph on the topic by Lawrence Schweinhart, Jeanne Montie, Zongping Xiang, William Barnett, Clive Belfield, and Milagros Nores.

Experimental Design

To conduct the High/Scope Perry Preschool study, David Weikart and his colleagues in the Ypsilanti public school system identified 123 young African American children in Ypsilanti, Michigan, living in poverty and assessed to be at high risk of school failure. They randomly assigned them to a program group and a no-program group, operated a high-quality preschool program for the program group at ages 3 and 4, and collected data on both groups annually from ages 3 through 11 and at ages 14, 15, 19, 27, and 40.

Sample Selection and Group Assignment

This study has followed the lives of 123 persons who lived in the attendance area of the Ypsilanti, Michigan, school district's Perry Elementary

School, which is located in a predominantly low-income African American neighborhood. Project staff identified a pool of African American children for the study sample from a census of the families of students then attending Perry School, referrals by neighborhood groups, and door-to-door canvassing. Project staff identified families of low socioeconomic status, which was defined by their low scores for parents' years of schooling, parents' occupational levels, and rooms per person in their household. They used the Stanford-Binet Intelligence Test to assess the intellectual performance of the young children of families of low socioeconomic status. They selected for the study children with low intellectual performance scores but no evidence of organic disability, at this initial testing. Only three families with children identified for the study refused to participate in it. The longitudinal study had 123 participants. Children entered the study in five successive classes annually from the fall of 1962 to the fall of 1965. Staff randomly divided the children in each class into those enrolled in the preschool program and those not enrolled in any preschool program. Program-group children attended the preschool program at ages 3 and 4, except for the first class of children, who attended only at age 4.

This study's ability to assess the effects of the preschool program even many years later is because of an experimental design in which study participants were randomly assigned to a program group enrolled in the preschool program or a no-program group not enrolled in any preschool program. After selecting children for a class in the study sample each fall from 1962 to 1965, project staff assigned them to program and no-program groups by identifying pairs of study participants matched on initial Stanford-Binet intellectual performance scores and assigning pair members to either of two undesignated groups. They exchanged one or two pair of members per class to match the groups on mean socioeconomic status, mean intellectual performance, and percentages of boys and girls. They randomly assigned one group to the program condition and the other to the no-program condition. As part of the initial assignment procedure in later classes, they exchanged one or two pair of members per class to reduce the number of children of employed mothers in the program group, because it was difficult to arrange home visits with them.

They assigned younger siblings to the same group as their older siblings to prevent the preschool program from affecting siblings in the no-program group. Statistical analyses indicate that these exchanges did not appreciably affect the findings of this study.

The assignment procedures make it highly probable that group comparisons reflect the effects of the preschool program. Comparisons indicating that groups were not significantly different on various background characteristics make it even more likely: Stanford-Binet intelligence quotient (IQ) at study entry, gender, family socioeconomic status, single-parent status, fathers' employment status, mothers' and fathers' years of schooling, children in family birth order, child's and mother's age at study entry, and rooms in home at study entry. The two groups differed significantly (with a two-tailed probability of less than .05) at study entry only on maternal employment (9% of the program group vs. 31% of the no-program group), based on the exchanges that moved them from the program group to the no-program group. Maternal employment at study entry was not correlated more than .13 with any of the major outcome variables, but nevertheless it was used as a covariate in the outcome analyses reported here.

The Preschool Program

High/Scope Perry Preschool Program teachers conducted daily 2½-hour classes for children on weekday mornings and made weekly 1½-hour home visits to each mother and child on weekday afternoons. The 30-week school year began in mid-October and ended in May. Of the 58 children in the program group, the 13 in the first class participated in the program for 1 school year at age 4, and the 45 children in subsequent classes participated in the program for 2 school years at ages 3 and 4. The four teachers in the program served 20 to 25 children each school year. This ratio was set to accommodate the demands of the weekly home visits. Between 1962 and 1967, 10 teachers certified to teach in elementary, early childhood, and special education served in the program's four teaching positions. During the years, 7 White and 3 African American women served as teachers, and at least 1 African American teacher was always on the staff.

High/Scope Perry Preschool Program staff developed a systematic approach to classroom and home visit activities that had both teachers and children defining and initiating children's learning activities. Originally called the Cognitively Oriented Curriculum to distinguish it from approaches that did not emphasize cognitive development, the education model was later named High/Scope. From the beginning, the program staff supported the development of young children's cognitive and social skills through individualized teaching and learning. They continued to develop the educational model as the program operated from 1962 through 1967, building on insights from their classroom experience and their review of the studies of Jean Piaget, Sara Smilansky, and others.

The High/Scope early childhood educational model, which was used in the Perry Preschool classroom and home visits, was and is an open framework of educational ideas and practices based on the natural development of young children. Drawing on the child development ideas of Piaget, it emphasizes the idea that children are intentional learners, who learn best from activities that they themselves plan, carry out, and review afterward. Adults introduce new ideas to children through adult-initiated small- and large-group activities. Adults observe, support, and extend the children's play as appropriate. Adults arrange interest areas in the learning environment; maintain a daily routine that permits children to plan, carry out, and review their own activities; and join in children's activities, asking appropriate questions that extend their plans and help them think about their activities. They add complex language to the discussion to expand the child's vocabulary. Adults encourage children to make choices, solve problems, and engage in activities that contribute to their intellectual, social, and physical development.

This study has accumulated an unusually rich and comprehensive data set on young people growing up in poverty, with variables representing their status from birth through childhood and adolescence to early adulthood and midlife. The many variables encompass demographic characteristics, test performance throughout childhood and adolescence, school success, crime, socioeconomic success, health, family, and personal development. Across the 48 measures of 123 cases, a median 7 cases (5.7%) were missing. At the age 40 interview,

of the 123 original study participants, 112 participants were interviewed, 4 living participants were not, and 7 participants were deceased. Criminal justice and social services records were considered to have no missing cases because the names of all the study participants were included in these searches, and the lack of a record indicated no arrests or no social services, although it is possible, of course, that some information was recorded in agencies whose records were not searched.

The analytic techniques presented in this entry are based on comparisons of the program group and the no-program group with statistical adjustments to compensate for the effects of seven background covariates—participants' gender, Stanford-Binet IQ at study entry, mother's schooling, father's occupational status, household rooms per person, mother's employment, and father at home. Group differences in outcome variables, which were statistically adjusted by the seven covariates, were examined by binary logistic regression analysis for dichotomous variables, ordinal regression analysis for ordinal variables, and ordinary least-squares regression analysis for normally distributed interval variables, such as tested performance. Except for tested performance, the distributions of most outcome variables were positively skewed to the right, that is to say, L-shaped. These distributions were truncated by dividing the variable into equal-sized segments and then analyzed as above. A group difference is identified as significant if it is statistically significant with a one-tailed probability of chance occurrence of less than .05, using one-tailed probabilities because the study's hypotheses are clearly directional.

Findings

The program group and the no-program group had significantly different outcomes through age 40 in education, economic status, crime, and convictions. Data were also analyzed by causal modeling and cost-benefit analysis.

Education and Economic Status

The program group significantly outperformed the no-program group on highest level of schooling completed (77% vs. 60% graduating from high school or adult high school or obtaining a

General Educational Development [GED] certificate). Specifically, a much larger percentage of program than no-program females graduated from regular high school (88% vs. 46%). This difference was related to earlier differences between program and no-program females in the rates of treatment for mental impairment (8% vs. 36%) and retention in grade (21% vs. 41%). The program group significantly outperformed the no-program group on various intellectual and language tests from their preschool years up to age 7, school achievement tests from ages 7 to 14, and literacy tests at ages 19 and 27. The program group had significantly better attitudes toward school than the no-program group at ages 15 and 19, and program-group parents had better attitudes toward their 15-year-old children's schooling than did no-program-group parents.

Significantly more of the program group than the no-program group were employed at age 40 (76% vs. 62%), especially males (70% vs. 50%), and at age 27 (69% vs. 56%), especially females (80% vs. 55%). The program group had significantly higher earnings than the no-program group, annually at ages 27 and 40 (medians of \$12,000 vs. \$10,000 at age 27 and \$20,800 vs. \$15,300 at age 40) and monthly at both ages (medians of \$1,020 vs. \$700 at age 27 and \$1,856 vs. \$1,308 at age 40). Significantly more of the program group than the no-program group owned their own homes at ages 27 (27% vs. 5%) and 40 (37% vs. 28%) and owned a car at ages 27 (73% vs. 59%) and 40 (82% vs. 60%). At age 40, significantly more of the program group than the no-program group had a savings account (78% vs. 50%), especially males (73% vs. 36%). At age 27, significantly fewer of the program group than the no-program group reported receiving social services at some time in the previous 10 years (59% vs. 80%).

Crime and Convictions

The study presents strong evidence of the program preventing lifetime arrests and subsequent prison or jail sentences. Compared with the no-program group, the program group had significantly fewer arrests by age 40; 55% of the no-program group compared with 36% of the program group were arrested 5 or more times. Compared with the no-program group, the program group had

significantly fewer lifetime arrests for violent, property, and drug crimes by age 40: 48% versus 32% ever arrested for violent crimes, 58% versus 36% for property crimes, and 34% versus 14% for drug crimes. Program group members were convicted and sentenced to significantly fewer months in prison or jail by age 40 than were no-program group members, with 28% versus 52% sentenced to any time in prison or jail. Regression analyses found no group-by-gender interaction effects for any crime or sentencing variable. In childhood, according to ratings of kindergarten through 3rd-grade teachers, the program group had engaged in personal misconduct (e.g., absences, stealing, and swearing) and school misconduct (e.g., resistant to teacher, manipulating adults, and influencing others toward troublemaking) significantly less frequently than the no-program group.

Causal Model and Cost-Benefit Analysis

A causal model was developed that takes into account the temporal ordering of the variables. Because of the small sample size for such complex analyses, this model is suggestive rather than definitive. It suggests that the following causal path is the route through which preschool program effects are transmitted to arrests by age 40. Preschool experience directly improves study participants' early childhood intellectual performance, which is also positively affected by family socioeconomic status. Their early childhood intellectual performance improves their school motivation in elementary school, and together, these variables reduce the number of years spent in programs for mental impairment. Because of their early childhood intellectual performance and years spent in programs for mental impairment, they have higher literacy scores as they leave high school. Their school motivation leads them to complete a higher level of schooling. Because they have completed a higher level of schooling, they have higher monthly earnings at age 40 and fewer lifetime arrests.

In constant 2000 dollars discounted at 3%, the return to society per participant is \$244,812 on an investment of \$15,166: \$16.14 per dollar invested. Four-fifths of that return went to the general public, and one-fifth went to each participant. Of the public return, 88% came from crime savings, and

the rest came from education and welfare savings and increased taxes paid on higher earnings. A full 93% of the public return was because of the reduced crime rates for program males. Male program participants cost the public 41% less in crime costs per person, which is \$732,894 less (in undiscounted 2000 dollars) during their lifetimes. Preschool program participants earned 14% more per person than those who did not attend the preschool program—\$156,490 more during their lifetimes (in undiscounted 2000 dollars).

Discussion

Because of the random assignment and low attrition, this study has strong internal validity. The external validity or generalizability of the study findings extends to those programs that are reasonably similar to the program: a preschool education program run by teachers with bachelor's degrees and certification in education, each serving up to 8 children living in low-income families. The program runs 2 school years at 3 and 4 years of age, uses the High/Scope educational model, with daily classes of 2½ hours or more and teachers visiting families at least every 2 weeks. The High/Scope Preschool Curriculum Comparison Study, which immediately followed this study, suggests that curriculum had a lot to do with the findings. This study found that young people born in poverty experience fewer emotional problems and felony arrests if they attended a preschool program that used High/Scope rather than intensive direct instruction.

The conclusion from the research presented in this entry is that high-quality preschool programs for young children living in poverty contribute to their intellectual and social development in childhood and their school success, adult economic performance, and reduced commission of adult crime. The simple implication of this study and several others like it is that all young children living in low-income families should have access to preschool programs that have features reasonably similar to those of this program.

PHYSICAL HEALTH CONSEQUENCES OF VICTIMIZATION

The physical health consequences of victimization are an area that has only recently received attention in victimization research. The lack of research may be attributed to the fact that many individuals do not report being a victim, individuals may not characterize themselves as victims, and many do not seek medical help or assistance with injuries sustained through the victimization. Understanding the extent to which victimization results in physical health problems is important and necessary, so that resources can be better allocated and victim-assistance programs will be better equipped to help victims deal with the aftermath of being victimized. This entry provides a definition of the physical health consequences of victimization, the types of physical injuries victims often suffer, the prevalence of such physical consequences, and finally ends with prevention efforts currently in place to help reduce the number of physical injuries that occur as a result victimization.

Definition

Physical health refers to anything that has to do with the body as a physical entity. Therefore, the physical health consequences of victimization can be defined as any harm or injury that occurs to the body as a result of being victimized. These health consequences can be acute, which means they have a sudden onset and only last a short time, or they may be chronic in nature, lasting a long period of time. Also, there are stress-related health problems, which occur as a result of a person's inability to cope with victimization. Physical health problems that follow victimization can range from little to no problems, all the way up to numerous serious injuries or in rare cases, death.

Types of Physical Health Consequences

Acute Physical Health Problems

The most common types of physical injuries sustained by victims are acute in nature. These types of injuries typically occur immediately and are of a short duration. Whether a victim will experience some of these health injuries depends on a variety of factors, including the type of victimization and level of force used. Examples of these types of injuries include, but are not limited to, broken bones, bruises, cuts, dental damage, dislocated joints, head injury, lacerations, scratches, sprains, strains, and welts.

Chronic Physical Health Problems

Although they occur less frequently, chronic health problems can occur as a result of victimization. These types of injuries range in severity, and persist over time for the victim. Once again, whether or not a victim experiences chronic health problems depends on the type of victimization and level of force used, as well as other factors. Examples of chronic health problems include, but are not limited to, chronic pain in the back, neck, and head; gastrointestinal problems; gynecological problems; contraction of HIV or sexually transmitted diseases (STDs); infertility; and pregnancy.

Stress-Related Health Problems

Although most individuals have an amazing ability to adapt to everyday stressors and stressful

situations, sometimes just one event can push an individual over the edge, or a culmination of factors can lead to a person reaching their limit of what they can handle. Whereas stress often affects psychological health, the inability to deal with stress often manifests itself in the form of physical health problems. Such problems can include sleep problems (e.g., insomnia, nightmares, and fatigue), chest pain or heart racing, headaches, gastrointestinal disorders, and weight change.

Prevalence

The prevalence of physical health consequences of victimization can vary according to the type of population being studied, as well as the type of victimization and the survey instrument that is used. Patricia Tjaden and Nancy Thoennes studied 8,000 men and 8,000 women in their National Violence Against Women Survey (NVAWS) and found that for rape victims, 31.5% of females and 16.1% of males were physically injured. In the case of physical assault victims, 39% of women and 24.8% of men reported injured as a result of the victimization. Victims in the NVAWS most commonly reported minor types of injuries, such as scratches and bruises, whereas few reported more serious injuries such as broken bones, sprains, and strains.

In a report by Fisher, Cullen, and Turner using the National College Women Sexual Victimization Study (NCWSV), approximately 20% of female rape and attempted rape victims reported being injured. Most injuries were relatively minor and primarily consisted of minor bruises, black eyes, cuts, swelling, and chipped teeth. For other types of victimization, 0% of completed sexual contact without force victims and 16.7% of threatened rape victims reported sustaining an injury as a direct result of the victimization.

Prevention

Prevention efforts have been made at multiple levels of the victimization event. First, prevention efforts have sought to reduce victimizations from occurring in the first place, through increasing awareness and introducing environmental changes to areas that are favorable to crime. Second, prevention programs are in place to help educate individuals on protecting themselves and avoiding

situations conducive to victimization, as well as to help increase knowledge on different types of victimization in general. Finally, secondary prevention efforts have been put in place to decrease the impact of victimizations after they have occurred. Programs that seek to match up victims with victim-assistance programs soon after a victimization has occurred and hospital treatment referrals are both used to help the victim after victimization.

usually the first contact a victim has with the criminal justice system. Depending on how this contact goes, victims will have either a positive or negative view of the criminal justice system.

In criminal proceedings, the state is viewed as the injured party, and so it may be easy to lose sight of the pain and suffering experienced by victims of crime. In an effort to protect society, the needs of persons most directly impacted by a crime might be overlooked. Recent legislation and victim advocacy has had an impact on how the criminal justice system, as a whole, treats victims. And because the first line of contact is the police, they play a key role in accomplishing a victim-centered approach to the criminal justice system.

How police respond to and interact with victims ultimately has an effect on the outcome of the case. It may also impact the healing process of the victims, the degree of respect victims have for the police, and the level of victim cooperation with the police and others in the criminal justice system. At the same time, the police have a job to do. They are the fact-finders, the ones who need to investigate crimes in order to solve them. The tension between providing services to victims and doing their jobs often creates friction between the two groups.

Police officers are typically trained in providing service information to victims, but they are not victim's advocates. A victim's advocate may be associated with a police department, but it does not mean that the average police officer can provide the same services to the victim that is provided by the advocate. For example, often the advocate will accompany the victim to court. However, because the police officer will need to testify at the trial, he or she cannot also accompany the victim (who is now considered a witness) to court.

Police do not discover most crime; they rely on victims and witnesses to report it. Therefore, it is imperative that victims and witnesses feel comfortable with the police to increase reporting. Several strategies can be employed to get victims/witnesses to report including providing police with adequate training programs to increase their sensitivity and awareness concerning victims' needs, returning property to victims more quickly, updating victims periodically about the status of their cases including informing the victim when the case is solved, and protecting victims/witnesses from intimidation. Some departments have developed comprehensive

POLICE AND VICTIMS

A mutual, yet often strained, relationship exists between police and victims. Police officers are

counseling programs and victim-assistance programs within the police department to encourage reporting and then to have follow-up services available to the victims after they report. And in some jurisdictions, police departments are moving toward an automated system of reporting in an effort to make it easier for victims of all types of crime to report. However, the more severe the crime, the more likely the victim will need to speak directly to an officer, and in these situations, it is best to have the full services available to the victim to balance the needs of the victim and the police. Also, police need to be trained in successful interviewing tactics to interview victims of crime. In cases such as sexual assault or domestic violence, the interviewing skills of police officers need to be highly tuned to solicit the information needed from the victim, without causing more harm. It is important in these situations for the police to let the victim decide when and where the interview will take place; in consultation with the victim make a decision about who should conduct the interview—a police officer, rape counselor, or victim's advocate; build a rapport with the victim, meaning that the interview must not be rushed; and speak to the victim with mutual respect and dignity.

It is also important for police to understand how victims respond to victimization. For the police to help victims and to get victims to help them with their open cases, there needs to be comprehension and empathy on the part of the police. There is not one universal response to victimization; thus, the police need to be skilled in how to identify appropriate reactions to victimization, which include the emotional toil that will manifest after the crime has occurred. The traumatic effects of the crime are often referred to as a crisis, and police need to be trained in crisis management. Additionally, special populations may be victimized that also need additional care. Included would be elderly victims, victims with disabilities, ethnically diverse victims, and secondary victims (victims who are not the primary victim but who experience the repercussions of the crime). This group would include family members, friends, co-workers, neighbors, and in some cases, the public.

Finally, it is important that police know of other services for victims either on the local or federal level. Police should be informed about the services available and be able to tell the victim

generally what services exist. If the police department has a victim's advocate, then a more detailed explanation of the services and the actual providing of services would come from this office.

Police and victims have a special relationship that sometimes is strained. The relationship is one of mutual concern and need. Both parties rely on the other when a crime occurs. With professional, annual training, police can move this often strained relationship into one of mutual respect and cooperation. The primary goal of the police is to protect its citizens, and when this protection is violated, the police must be able to console and provide services to victims to restore their faith in society. Great care has been given in many jurisdictions to include victim's advocates as part of police departments to ensure that victims are provided the services they need whether the services are provided directly by the police department or by some auxiliary unit that has special training and knowledge in a particular service area.

POLICE CRIME PREVENTION UNITS

Beginning with the establishment of the London Metropolitan Police Department, the modern system of policing has existed for more than 150 years. During that time, several key objectives have continued to serve as cornerstones of traditional policing ideals and efforts. Without a doubt, crime control has always been one of those objectives. In fact, it can easily be argued that controlling crime is the main objective of policing. With that in mind, there has been a long-standing focus on crime prevention in policing, as well. There is no better way to control crime than to

prevent it before it even occurs. Although crime-prevention techniques have historically been used by police departments in a general fashion, specific police crime-prevention units have only begun to surface in the last few decades. The late 1970s through the early 1980s observed the birth and development of community-based policing. One main concern of the community policing era is a strong focus on crime prevention. At the same time, problem-oriented policing has been quickly growing in popularity as an effective methodology for analyzing and responding to specific crime problems, especially community-wide crime problems. It was through the combination of community-oriented policing and problem-oriented policing that police crime-prevention units were born. Since the mid to late 1980s, crime-prevention units have become an integral part of policing.

Community-Oriented Policing

In America, a shift in policing ideology occurred during the late 1970s and early 1980s. Police departments began to move away from the more traditional professional model of policing, which focused on strong centralization, training, and specialization. Although it is beneficial in many ways, the professional model created a barrier between the police and the community they served, resulting in the failure to address community needs and problems appropriately. This dilemma led to the birth of the community-oriented policing (COP) model. The COP model focuses on direct communication between the police and the community in an effort to solve long-term crime problems. With this model, more emphasis is placed on the police acting as problem solvers rather than the more traditional crime fighters. Police departments and the surrounding communities work together in an effort to develop crime-prevention strategies that address the causes of crime, rather than simply deal with their outcomes.

Problem-Oriented Policing

Championed by Herman Goldstein in the late 1970s, problem-oriented policing (POP) is a method of policing in which officers are encouraged to use problem-solving techniques as a means of understanding and dealing with crime. Rather

than simply responding to crimes as individual incidents, police departments focus on the entire criminal event, getting at the core issues that cause crime. One key technique used with POP is referred to as SARA. SARA stands for scanning, analyzing, responding, and assessing. With techniques such as SARA, police departments can fully investigate crime problems and develop the most effective solution. These efforts allow for a preventive approach to policing, as many problems can be solved with preemptive solutions. POP is often directly associated with community-oriented policing. In fact, most police departments use the two methodologies together to analyze, investigate, and solve widespread community crime-problems.

Police Crime-Prevention Units

It has become common practice for many police departments to adopt COP/POP methodologies in an effort to develop strategies that target specific types of crime. In doing so, they often initiate specialized crime-prevention units. Typically, these units are designed in a manner that allows the police to work directly with members of the community in an effort to prevent crime problems within the community. The main goal of police crime-prevention units is to understand fully the types and extent of crime within the community, so that effective crime-prevention strategies can be developed. To achieve that goal, police crime-prevention units pay special attention to collecting and analyzing community crime data. The benefits of examining crime data are twofold. First, it provides the police with an understanding of the crime hotspot areas. This allows them to focus more attention on the areas that need it most. Second, it aids the police in the development of crime-prevention programs. Most police crime-prevention units offer different categories and/or types of prevention programs through which the police and community can work together to reduce crime. Although a large variety of crime-prevention programs is offered, the most common programs fall into only a few categories. Some of these programs are described below.

Citizen-Involvement Programs

Coinciding with the central theme of community-oriented policing, the most predominant types of

programs offered by police crime-prevention units are citizen-involvement programs. These types of programs most typically involve the police teaching citizens techniques that allow them to recognize potential criminal activity and secure their persons and property against potential offenders. Individuals are not encouraged to interact directly with offenders, but instead they are advised to contact the police on witnessing any potential criminal activity. Essentially, these types of programs allow citizens to take a proactive role in crime prevention while maintaining their own personal safety.

The most common citizen-involvement program employed by the police crime-prevention units is the Neighborhood Watch program. With Neighborhood Watch programs, citizens join formal police-trained watch groups within their neighborhood (typically restricted to one or two streets). Watch group members monitor the homes and public areas within their neighborhood, remaining alert to suspicious and/or potential criminal activity. If suspicious activity is observed, then the police are notified. Neighborhood Watch programs allow citizens and the police to work together to prevent crime before it occurs.

Many police crime-prevention units also offer business watch programs. With business watch programs, businesses in close geographic proximity form groups, similar to Neighborhood Watch groups. Employees of the businesses within the watch group are trained by the police to recognize and report suspicious individuals to both the other businesses in the group and the police. As with the Neighborhood Watch program, members of the business watch program communicate with and assist the police in an effort to prevent crime.

Educational Programs

The cornerstone of all police crime-prevention units is education. Although education is a continuous theme throughout relatively every police crime-prevention program, the sole purpose of certain programs is to educate. Typically with education programs, specially trained police officers lead informational sessions for members of the community, providing them with specific facts and tips about how to react in certain situations. Police crime-prevention units across the United States use a plethora of various education programs, varying in both subject and intended audience.

One of the longest running and most famous police-led education programs is the Drug Abuse Resistance Education (D.A.R.E.) program. Founded in 1983, D.A.R.E. is designed to teach adolescents about drugs and violence, providing them with tips about how to resist peer pressure. D.A.R.E. has been implemented in schools across the United States, as well as numerous other countries around the world. The goal of D.A.R.E. is to reach children before they participate in criminal activity.

First established in 1989, a more recently developed crime-prevention education program is the Rape Aggression Defense (R.A.D.) program. Though R.A.D. has not been as widely implemented as the D.A.R.E. program, it is quickly growing in popularity among police crime-prevention units. Using classroom-style lectures and physical training, the R.A.D. program is designed to teach women to recognize, avoid, and/or defend themselves against physical and sexual assault. A similar program, referred to as r.a.d.KIDS, teaches children how to recognize and escape violent situations.

Personal Safety Programs

Borrowing from many traditional theories of crime prevention, police crime-prevention units often offer programs that attempt to reduce the opportunity for criminal activity. Unlike citizen involvement and education programs that focus on providing individuals knowledge of how to react when coming into contact with an offender, personal safety programs are designed to prevent crime by directly influencing the targets of criminal offenders. Employing a broad spectrum of crime-prevention techniques, police crime-prevention units greatly reduce or even completely remove the attractiveness of potential targets/victims. Although these programs may not be as well known, they are vital in the police's effort to prevent crime.

Some of the most theoretically based types of programs offered by police crime-prevention units are building project assistance programs. With these programs, a police crime-prevention unit provides planning assistance during the construction and/or renovating phases of home development, and they can be tailored to assist private citizens, public housing developers, or even private contractors. These programs employ the concepts of crime prevention through environmental design

(CPTED) and defensible space to help design homes and neighborhoods that can be more easily defended against burglary and other property crimes. Essentially, these programs help protect homes and property by reducing their attractiveness as potential targets.

Police crime-prevention units also have several more direct personal safety programs. One of the most common personal safety programs is the police escort program. As its name implies, a police escort program simply offers police escorts for individuals who fear for their safety. Most typically, these programs are offered in and around college and university campuses. During specific hours of the night, students can contact the campus or local police and ask for an escort to their car, dormitory, or any other place on campus. This program serves to prevent crime by completely eliminating the attractiveness of potential targets. Rarely will an offender attack or rob someone who is with a police officer.

Property Identification Programs

Although the main focus of police crime-prevention units is to develop and use preventive techniques and programs, they often offer several programs that do not directly serve to prevent crime. These programs do have a crime-control function, however, but most typically only help once a crime has occurred. One of the most common programs that fit this model is the property registration program. Almost every police department offers free property registration services with which individuals can bring items in to register. The idea behind property registration programs is that if registered items are stolen, they can be identified and returned if found by the police.

The most common property registration programs focus on items that are most frequently targeted by thieves. This includes bicycles, laptops, and other portable electronic devices. Individuals bring their items into the police department and complete a registration form, describing the item and recording its serial number. Often, the police also provide them with equipment that can be used to engrave their item with a number, name, and so on. This strategy has become common practice on college and university campuses, as these areas are major targets for theft.

International Crime Prevention Units

Crime prevention is by no means limited only to the United States. In fact, many crime-prevention theories and programs that have been implemented in the United States originated in England and the Netherlands. Furthermore, many countries also use crime-prevention units. However, unlike crime-prevention units in the United States, which are most often localized to city and municipal departments, units in other countries are also frequently components of larger national departments. For example, in England, the Home Office offers programs that provide information and tips about how to prevent crime. Likewise, the New Zealand Ministry of Justice and the Dutch Centre for Crime Prevention and Safety both offer many of the same programs implemented by U.S. police departments. Similar units are continuously being developed in numerous other countries around the world.

POLICE FATALITY REVIEW TEAMS

Criminal homicide is considered the most heinous of all crimes. The use of fatality review is critical to

prevent various types of criminal homicides that affect both police officers and citizens. Fatality review can be defined as the careful and deliberative process of collecting, documenting, and examining the circumstances and factors that surround a criminal homicide. This entry briefly discusses the purposes and goals of fatality review regarding criminal homicides in general. Then, it discusses the formal data-gathering and review procedure used to examine police officer deaths that occur in the line of duty and the impact of this information. Last, it touches briefly on police participation on fatality review teams designed to investigate specific homicides such as domestic homicide and child deaths.

Purposes and Goals

The use of fatality review and participation on fatality review teams by law enforcement is critical to provide insight into criminal homicide incidents for preventing future deaths. Law enforcement agencies are involved in two distinct types of fatality reviews. The first is their formal case review and reporting procedures to the Uniform Crime Reporting (UCR) Program when a police officer is killed in the line of duty. The second is their participation on domestic violence and child death fatality review teams. Both the review of police homicides and those of civilians share the following two purposes: (1) to identify and examine the events and details that surrounded the homicide and (2) to use this learned knowledge to change and improve laws, policies, and police protocols. Each of these purposes leads to two common goals: improving the safety of police officers and civilians and preventing future injuries and deaths.

Reviewing Police Deaths

Each year in the United States, an average of 50 officers are feloniously killed in the line of duty, and approximately another 80 to 100 more are accidentally killed. The careful and deliberative process of documenting the factors that may have influenced the tragic outcomes of injury and death is a logical step that provides crucial insight into what went wrong. This process is known as fatality review.

The formal review of police fatalities is conducted by the Federal Bureau of Investigation (FBI) and began as part of their UCR Program in 1937. From

1937 to 1960, the UCR Program collected data, which reviewed brief statistics on law enforcement officers killed in the line of duty. Then in 1971, the UCR Program expanded the data collection to include more specific details about the incidents in which officers were feloniously killed and assaulted. These new comprehensive data were used to produce two reports annually, which were later combined into one annual publication, *Law Enforcement Officers Killed and Assaulted* (LEOKA).

The UCR Program uses three types of reporting procedures to learn of a police officer's death. The first and most common method is direct reporting to the FBI by the agency in which the officer worked. A second type is when an officer death occurs, the local FBI field division from the area reports the incident. Last the Bureau Justice Assistance Administrator of Public Safety Officer's Benefits and nonprofit organizations that are devoted to supporting families of fallen officers report to the UCR when they are made aware of a death in the line of duty.

At the local level, when a police officer is injured severely or killed in the line of duty, his or her agency will compile an investigative team to review the circumstances surrounding the incident. This information is then submitted to the UCR program as both notification of the incident and the preliminary data. When the FBI receives this notification, they send LEOKA staff to conduct their own in-depth gathering of information surrounding the circumstances of the death, which includes but is not limited to obtaining pertinent criminal history, and investigating variables such as type of call answered, type of weapon used, and type of patrol officers were on. The purpose of the LEOKA staff investigation is to ensure that for each case all the data gathered is pertinent to the LEOKA and consistent for each case, allowing for continuity across cases and more comparative analyses.

This information gathered by the UCR Program and included in the LEOKA report is used by law enforcement analysts and trainers to improve the quality of police safety training and ultimately save lives. It is also used to change laws and policies concerning police safety and procedures. For example, Florida just recently passed the "Move Over Law." This legislation was based on fatality review information that demonstrated many police injuries and deaths were a result of being struck by passing cars during routine traffic stops. The law

instructs drivers to move over a lane when passing police officers conducting stops, and the failure to do so is now a moving violation.

Domestic Violence and Child Death Fatality Review Teams

Both domestic violence homicides and child deaths caused by abuse and neglect are unique types of criminal homicides. These homicides are generally a result of repeat victimization that often increases in frequency and severity over time, and without proper intervention it often culminates into a homicide. For this reason, communities around the country have developed fatality review teams to review systematically the events and interventions that occurred in these cases prior to the homicide. Law enforcement agencies participate on these teams because it provides them with valuable insight into the effectiveness of their prior interventions and how to improve their response to prevent homicides in future cases.

who has experienced some sort of physical, mental, or emotional harm from another person, group of persons, or entity (i.e., corporation or nation), it does not mean that all victims are viewed as such by society. For most of history, access to the legitimate victim label was based on people's position in society. Society's ability to reject marginalized groups systematically, such as people of color, women, and children, has prevented access to victim services and restitution to nonlegitimate victims. In addition, victim politics frequently ignores secondary victims, such as family members of offenders, family members of victims, and providers working within these populations. Although grassroots organizations, such as the Abolishment Movement, Civil Rights Movements, Women's Rights Movement, and the Gay and Lesbian Movement, were instrumental in redefining legitimate victimization and creating entrée for marginalized populations, still some people experiencing victimization from persons or entities still do not have recourse because they are not considered legitimate victims.

Legitimate Victims

Throughout history, the definition of legitimate victim has changed, and traditionally, marginalized populations, such as people of color, women, and children, have not had access to the legitimate victim status. Historically, one of the first instances of this is the framing of Native Americans as "savages" and a threat to White colonizers. The non-victim label permitted colonizers to oppress Native Americans through violence and removal of land. Similarly, the frame of African Americans as property during slavery allowed White slave owners to rape, brutalize, and murder African Americans. Because African Americans were not legitimate victims, this fact denied these victims access to legal recourse and aided the dismantling of families through child removal and placement of persons in the economic market. In addition to personal actions of victimization, the United States government has used its ability to define appropriate victim categorization during World War II with the legal internment of more than 100,000 Japanese and Japanese Americans.

Fortunately, many civil rights movements during the 1960s and 1970s were able to bring some

POLITICS AND VICTIMS

Politics and victims, or victim politics, refers to how victim discourse is produced to identify the appropriate characteristics of victims and who has access to the legitimate victim label. Although technically, a victim is a person or group of persons

of these stories of victimization into the public discourse and bring into the legitimate victim label populations previously denied access. For example, women's status as male property prevented women from being viewed as a victim because men could have the right to act in any manner desired toward women. The Women's Right Movement fought to bring into the public sphere women's victimization through intimate partner abuse, sexual assault, and violence against women in general. The empowerment of women experiencing victimization led to the introduction of women's voices in the courtroom, and those voices influenced the criminal legal system. However, not all women's voices were brought into the public sphere, as only White women who fell into the appropriate roles of woman and mother were considered legitimate victims. Victim discursive politics excluded women of color, immigrant women, and women who did not fit the real victim mold (sex workers, single women, etc.). The same victim discursive politics were applied to sexual assault victims. Because real rape only occurred between a male stranger and an innocent female, it denied access to the "victim" label for acquaintance rape victims, marital rape victims, and male victims.

Blaming the Victim

The inclusion of traditionally excluded people into the victim label created a backlash that included blaming the victim for his or her crime. For instance, once rape victims' voices were heard in the criminal legal processing system, the victim label constricted to include only women who were legitimately considered "real victims" of rape. More specifically, women who had been drinking or had sexual backgrounds were considered partially responsible for their victimization. In addition, women involved in abusive relationships often were blamed for the continual violence because "she could just leave." Blaming the victim for the crime has adverse repercussions because if the victim does not feel that he or she fits into the appropriate victim role, then it may create a barrier to the criminal legal system and victim services. An example of this is African American women, whose lack of access to the appropriate victim role and history of institutional racism may lead to hesitancy to use police and other victim-centered services.

New Victim Politics

The legitimate victim discourse has led to the notion that being a victim implies a weakness, vulnerability, or the inability to protect oneself. Therefore, recently there has been a call to end using the term *victim* and begin using the term *survivor*, because survivor connotes resistance and strength. Despite women's organizations embracing this transition, the term survivor has not been completely accepted, as some victim advocates argue that survivorship is a transformative process from victim to survivor, and not all victims are survivors. Thus, the definition of victim is fluid, and who has access to the legitimate victim status depends on multiple factors, which may be external to the actual victimization. Victim discursive politics will likely always be present and influence the validation of experience and access to services.

POSTTRAUMATIC STRESS DISORDER (PTSD)

Posttraumatic stress disorder (PTSD) consists of three clusters of interrelated symptoms: re-experiencing, avoidance/numbing, and hyperarousal. These symptoms develop after an individual experiences a

traumatic event. Traumatic events involve actual or threatened death or injury or a threat to an individual's physical integrity. Traumatic events can include events that one actually experienced or events that one witnessed. Examples of traumatic events include physical or sexual assault and abuse, combat, natural disasters, terrorism, and serious illness. According to the criteria for PTSD set forth in the *Diagnostic and Statistical Manual of Mental Disorders* (4th ed; DSM-IV), for an individual to develop PTSD, the person must respond to the traumatic event with feelings of intense fear, helplessness, or horror. In addition, to differentiate PTSD from temporary reactions to traumatic experiences, the individual also has to report experiencing symptoms of PTSD for at least 1 month, although in many instances symptoms can persist for years.

For an individual to meet criteria for PTSD according to DSM-IV criteria, he or she must experience at least one re-experiencing symptom, three or more avoidance or numbing symptoms, and two or more hyperarousal symptoms. Re-experiencing symptoms include recurrent unwanted thoughts, dreams, or memories of the trauma. Re-experiencing symptoms in children with PTSD may include engaging in play that involves traumatic themes or having frightening dreams without specific traumatic content. In adolescents, re-experiencing symptoms may include re-enacting the trauma in their behaviors (e.g., sexual acting out behavior in an adolescent who experienced sexual abuse). Some individuals also experience reliving phenomenon, which can include the sense that the trauma is re-occurring, illusions, hallucinations, or flashbacks. Avoidance symptoms include avoidance of reminders of the trauma including trauma-related thoughts, places, and activities, and conversations about the trauma. Some individuals may have amnesia that has no physiological basis for important aspects of the trauma. Numbing symptoms include difficulties experiencing or blunted expression of certain emotions such as love or happiness, feelings of detachment from others, loss of interest in previously enjoyed activities, and a sense of a foreshortened future (e.g., that one will not have a long life, have children, have a career, or have important relationships). Hyperarousal symptoms include insomnia, irritability, outbursts of anger, difficulty

concentrating, hypervigilance to danger cues, and an exaggerated startle response.

Prevalence

Epidemiological surveys of PTSD have primarily been conducted among adults in developed countries. The National Comorbidity Survey (NCS) and National Comorbidity Survey Replication (NCS-R) conducted among residents of the United States found estimated lifetime prevalence rates of PTSD of 7.8% and 6.8%, respectively. Obtained prevalence rates for PTSD in other developed countries have often been lower than U.S. samples. For example, an Icelandic study found a lifetime prevalence of PTSD of 0.6%, an Australian survey found a 12-month PTSD prevalence of 1.3%, and a German study found a lifetime prevalence of PTSD of 1.3%. It is unclear the extent to which these prevalence differences reflect true differences in prevalence rates of PTSD among individuals residing in these countries, as opposed to methodological or sampling factors.

Limited research examining the prevalence of PTSD is available in developing countries. Not surprisingly, research that has been conducted examining the prevalence of PTSD in developing countries, particularly countries with high levels of conflict or oppressive regimes, have found high prevalence rates of this disorder. For example, the prevalence of PTSD in a sample of Kosovar Albanians was 25%. A similar prevalence of PTSD of 24.8% was found in a sample of Rwandans. Finally, rates of PTSD found in Afghan samples in the 2000s have ranged from 20.4% to 43.1%.

Epidemiological surveys of PTSD among children and adolescents are lacking. Surveys conducted among children in the United States support that many children experience traumatic events, with prevalence estimates for trauma exposure ranging from 13% to 81%, depending on the sample used (e.g., inner-city children versus children residing in suburban areas) and traumatic events assessed. Children who experience traumatic events seem to be vulnerable to the development of PTSD with the risk of developing PTSD after a traumatic event among children estimated at 36%. There have been a few studies examining the prevalence of PTSD among older adolescents in the United States. These studies have found prevalence rates of PTSD ranging from 6% to 9%.

Risk Factors

The nature of the traumatic experience itself is one of the clearest and most consistent predictors of the development and persistence of PTSD. Traumatic events involving human agency, such as abuse, sexual assault, combat, or terrorism, are more likely than those not involving a human agent to result in PTSD. The severity of trauma exposure and trauma chronicity also relate to PTSD development and persistence. Some evidence indicates that trauma is cumulative in nature, such that individuals who experience multiple trauma experiences over the life span are at elevated risk for PTSD.

Pretrauma factors in general have not emerged as consistent predictors of PTSD. One consistent finding that has emerged, however, is that women are approximately twice as likely to meet diagnostic criteria for PTSD as men. These gender differences can be partially, but not completely, explained by differences in the types of trauma experienced by women as compared with men, particularly women's greater risk for experiencing sexual trauma, such as childhood sexual abuse and rape. In contrast, no consistent findings are available with regard to differences in PTSD prevalence among individuals of different ages and ethnic backgrounds. There is some evidence to support that those individuals with pre-existing psychopathology such as depression and substance use disorders are somewhat more vulnerable to developing PTSD following trauma exposure. Family psychopathology also seems to be associated with a slight increase in vulnerability to developing PTSD, although the extent to which this reflects a genetic vulnerability factor and/or factors or environmental vulnerability factors (e.g., a chaotic family environment) is unclear.

Individuals' peritraumatic responses seem to represent clear and significant risk factors for the development of PTSD, although the strength of the association found between these variables and PTSD may be somewhat inflated because of the reliance on retrospective reports of these responses. Peritraumatic responses associated with PTSD risk include the extent to which the individual perceives that his or her life was in danger during the trauma, with some studies finding that perceived life threat is more strongly associated with PTSD

than objective life threat during the trauma. The intensity of individuals' emotional responses during the trauma, such as whether the person has a panic attack or experiences feelings of helplessness, horror, or anger, also have been associated with increased risk of developing PTSD. Another peritraumatic risk factor associated with PTSD development is the extent to which an individual dissociates during the trauma. Indeed, a recent meta-analytic review found that peritraumatic dissociation had the strongest relationship with PTSD of all the risk factors analyzed.

Many posttrauma factors have been associated with the development, persistence, and severity of PTSD symptoms. A growing body of literature supports that the extent to which an individual experiences a loss of valued resources after trauma, including material possessions, interpersonal resources (e.g., time with loved ones), and intrapersonal resources (e.g., hope, self-esteem), is associated with risk for PTSD. Social support has also been consistently associated with PTSD risk and severity of symptoms. The coping strategies that an individual uses in managing the trauma also are clearly related to PTSD risk and severity. In particular, reliance on avoidance strategies in managing the trauma, such as wishful thinking (e.g., imagining that the trauma had not occurred), problem avoidance, and disengagement from trauma-related thoughts and feelings, are associated with PTSD symptomatology. The extent to which an individual experiences damage to many culturally valued beliefs has also been related to PTSD development and severity after trauma. Beliefs commonly affected by the experience of trauma associated with PTSD risk include belief that the world is a safe place, belief that other people are generally good and benevolent, belief in the trustworthiness of others, belief in one's own worth, and belief that life has meaning.

Prevention and Treatment

Given the frequency of the development of PTSD after trauma, as well as the often chronic nature of this disorder, a sizable body of research has focused on interventions to prevent the development of PTSD after trauma. The most extensively investigated preventive intervention is psychological debriefing. Psychological debriefing involves

reliving the event and ventilating of one's thoughts and experiences about the trauma in either a group or individual format within a few days of the traumatic event. Other preventive interventions include psychoeducation about trauma and trauma reactions, as well as brief cognitive-behavioral interventions. Unfortunately, these psychological interventions have not been found to be effective at preventing the development of PTSD among trauma-exposed individuals, and some evidence suggests that psychological debriefing may at times even have iatrogenic effects, perhaps by impeding natural trauma recovery. Several pharmacological agents have also been investigated in the prevention of PTSD. Of the agents investigated, propranolol, which is an antiadrenergic agent, shows the most promise at potentially reducing the development of symptoms of PTSD, particularly hyperarousal symptoms, when administered before or immediately after a trauma. Use of pharmacological agents to prevent PTSD presents many potential issues, however, including whether use of such agents may reduce the credibility of testimony of crime victims or impede appropriate responding in dangerous situations such as among soldiers and police and rescue workers.

With regard to the treatment of PTSD, cognitive-behavioral interventions are the most consistently empirically supported among adults. Cognitive-behavioral interventions have primarily been evaluated among individuals who have experienced rape, abuse, or domestic violence. There is also some evidence for the effectiveness of cognitive-behavioral interventions in children and adolescents with PTSD, although it should be noted that most of these studies have focused on individuals who experienced sexual abuse. Cognitive-behavioral interventions for PTSD generally consist of several components. Exposure is often a key component of these interventions. Exposure can include repeated and graduated exposure to avoided trauma-related cues as well as repeated exposure to the trauma memory through imaginal exposure. Cognitive restructuring is also often employed. Cognitive restructuring generally targets several trauma-related cognitions, including self-blame for the trauma, distorted cognitions regarding perceptions of one's safety, cognitions related to the trustworthiness of others, and inappropriate and excessive trauma-related guilt.

Finally, anxiety management strategies such as relaxation training and stress management are often used.

There is also some evidence to support the usefulness of pharmacological agents in the treatment of PTSD. Selective serotonin reuptake inhibitors (SSRIs) have the most evidence for their effectiveness in reducing symptoms of PTSD. However, treatment with SSRIs rarely results in full remission of symptoms. The atypical antidepressants nefazadone and trazadone are also used frequently to treat PTSD-related sleep disturbance, although these agents have not been extensively empirically evaluated. Finally, there is some evidence for the usefulness of atypical antipsychotics in the treatment of PTSD, particularly among individuals who experience extreme hypervigilance, anger, or dissociation.

PRESIDENT'S CRIME COMMISSION REPORT, 1967

The President's Commission on Law Enforcement and the Administration of Justice was created by Executive Order 1236 and was signed by President Lyndon Baines Johnson on July 23, 1965. The commission delivered its report, *The Challenge of Crime in a Free Society*, in early 1967. In popular shorthand, the commission was identified with its end date rather than the year of its creation, and its report became known as the 1967 President's Crime Commission Report. Its recommendations formed the basis for the 1968 Omnibus Crime Control and Safe Streets Act, which created the Law Enforcement Assistance Administration. The commission's work launched many of the innovations and foundational research into the criminal justice system that marked the decade of the 1970s.

Background

The commission was composed of 19 members appointed by the President. Under the leadership of Executive Director James Vorenberg, of the Harvard Law School, some 63 staff members, 175 consultants, and hundreds of advisors undertook the work of the commission. The staff members were drawn from a variety of positions in academia, policing, corrections, the court system, state planning agencies, and social service agencies. Many of the commission's staff members and advisers are today recognized as the preeminent scholars of criminal justice and criminology: Jerome Skolnick, O. W. Wilson, James Q. Wilson, Gilbert Geis, Egon Bittner, Al Reiss, Peter Rossi, Irving Spergel, Herman Goldstein, Don Gottfredson, Walter Reckless, Jackson Toby, Marvin Wolfgang, Thorstin Sellin, Karl Menninger, Patrick V. Murphy, Ray Galvin, and many others.

The backdrop to the commission's work was the rising crime rate of the mid-1960s, one of several widespread social changes that afflicted the decade. The commission was convened amid increased urban violence that accompanied the radicalization of the Civil Rights Movement. The urban riots of the "long, hot summers" of the middle part of the decade were only a small part of the crime problem, but race relations played a

large role in the exploration of the administration of justice. Citizen resistance to American military involvement in Vietnam was in its early stages, and it would not coalesce until after the commission delivered its report.

The commission was not the only entity examining the criminal justice system. The American Bar Association had been conducting a lengthy examination of the use of discretion within the system, and some of its findings fed the investigation by the commission. State-level planning commissions were also part of the effort. More importantly, the Supreme Court had abandoned its traditional *laissez faire* treatment of criminal justice operations, delivering a series of cases that exposed serious flaws in the administration of justice in all areas. *Gideon v. Wainwright*, *Mapp v. Ohio*, and *Escobedo v. Illinois* had already been decided; *Miranda v. Arizona* would be announced shortly after the commission's report was delivered.

Report and Recommendations

The work of the commission was conducted by several task forces, with some members serving in multiple areas. The primary areas reported in *The Challenge of Crime in a Free Society* (*Challenge*) were crime in America, juvenile delinquency and youth crime, the police, the courts, and corrections. In addition, special investigations were mounted into organized crime and several areas thought to contribute to the spiraling rate of crime, which included narcotics and drug abuse, drunkenness offenses, and control of firearms. Separate chapters on science and technology, the role of research, and a national strategy for crime control completed the commission's report. Supplemental Task Force Reports were issued in several areas, particularly the police, the courts, and corrections, which provided more detailed analysis, including more explicit justification for some of the recommendations reported in *Challenge*.

The opening chapter of the report linked crime with a wide range of urban social conditions, noting that three quarters of all reported crime occurred in cities. The contributory roles of poverty, urban renewal, the decline of family and community moral authority, disparate educational and work opportunities, and lack of medical and psychiatric services were outlined. After reviewing the

operations of the criminal justice system, the commission identified three primary requirements for improvement: adequate resources, public involvement and support, and a willingness to change.

Much of the commission's report on crime in America is familiar to modern readers. Multiple sources of data about offenders were delineated, as was the distinction between professional criminals and impulsive criminals. The commission mounted the first-ever independent victimization survey, the predecessor of today's National Crime Victimization Survey. It illustrated the vast underreporting gap between officially recorded crimes and those reported to the survey and documented the reasons for victim failure to report. The distinction between actual victimization and fear of crime was first explored, and it led the commission to conclude that the public's fear of crime was not without justification.

The Juvenile Delinquency section focused on slum conditions, family structure and discipline, the role of schools, employment opportunities, and official contacts with the components of the justice system. The 40 recommendations in this area touched on improvements in housing and recreation, involving youth in meaningful community life, and greater employment opportunities for youth. The most serious calls were to adjust welfare policy to strengthen families (including minimum income and child care) and to make substantial changes in the educational establishment to compensate for the effects of poverty and discrimination. Stricter limits on the use of the juvenile justice system, guidelines for police handling of juvenile cases, and greater alternatives for handling juvenile infractions were sought for the system itself.

The Police section noted serious deficiencies in the police on many fronts, including the low quality of education of serving officers, the inadequacy of supervision and command, and deficiencies in training, material, and information processing. The need to improve police relations with the community was heavily emphasized, particularly with minority groups within the community at large. Greater recruitment of minority officers and the creation of citizen advisory committees were recommended, but the primary emphasis on improvement fell on the areas of recruitment, training, and guidelines for action. Improved screening for character and education, modified fitness standards and residency requirements, minimum requirements for

both initial training and annual in-service training, and probationary periods for assessing on-the-job fitness were radical proposals at the time. They have been internalized into accepted professional standards during the years. A series of recommendations called for making scarce resources, such as crime laboratories and skilled investigators, available to small agencies, and it also called for coordinating police operations with municipal planning.

Like the police, the courts were also found to be understaffed for their work load, and in need of upgraded facilities and equipment. Standardization of practices concerning publicity, pretrial discovery, and plea negotiations were prominent concerns, as was a need for revision of sentencing practices. Better screening of court personnel, better education for judges, and comparable reforms among prosecutors were fundamental to improved salary conditions. State financing and better training for defense counsel, as well as earlier provisions of counsel for indigent defendants, were emphasized.

The corrections system of the mid-1960s handled an average of 1.3 million offenders each day and processed 2.5 million admissions each year. Then as now, prison conditions and the degree to which offenders were prepared to return to society were concerns. The commission conducted a national survey of the system to overcome the fragmentary nature of existing data, examining both institutional and community-based corrections. Enhanced screening and diagnostic resources to facilitate better decision making and explicit standards were urged across all aspects of the system.

The commission's recommendations included a caseload of 35 for probation and parole officials and vary according to the type and intensity of treatment. More extensive programs, more extensive training for personnel, and greater availability of resources including volunteers and "subprofessionals" were urged.

Recommendations for institutional corrections including smaller, flexible, community-oriented treatment focused on rehabilitation. Education and training programs were emphasized, along with graduated furlough programs to ease prisoners' transition back into society. Separate juvenile facilities and separate detention for persons awaiting trial were also strongly recommended.

Awareness of organized crime was one of the features of the 1960s, spurred in part by the Kennedy administration. The commission classified

the organized crime activities under two headings, catering to public demands and the infiltration of business and labor interests. Mob characteristics were outlined, as were the nature, scope, and limits of state and federal enforcement. The commission's recommendations in this area were far ranging, from witness protection to wiretapping legislation to structural changes in prosecution and investigative agencies, as well as establishing a joint congressional committee.

Although related to organized crime, drug offenses were widespread. Drug typologies and their pharmacological effects, smuggling and distribution mechanisms, enforcement capacities, and penalties for abuse were all outlined. Recommendations of enhanced enforcement capacity were balanced by those calling for flexible responses to the problem, which include the education and the medical professions as partners. The commission conducted a similar analysis of drunkenness, calling for noncriminal responses to the problem, the creation of detoxification centers, and aftercare programs.

The commission also reported the statistics of firearms violence and the patchwork of state and federal regulations of firearms. After reviewing the progun and antigun control arguments, the commission asserted the law of the day: that the Second Amendment did not guarantee individual ownership of firearms. (That finding has recently been overturned by the 2008 Supreme Court decision in *Heller v. District of Columbia*.) The commission urged that federal and state regulation of medium-heavy ordnance such as bazookas, machine guns, mortars, and antitank guns, as well as prohibition of certain categories of persons (habitual drunkards or addicts, those with mental illness or defect, and those with certain criminal convictions) from owning small arms. Regulation at the state level was urged, with a recommendation of federal registration after 5 years if necessary and permits required for sale and purchase of firearms.

Noting that the Justice Department was the only Cabinet position without a share of the federal research and development budget, the commission made extensive recommendations for research on operations (including manpower allocation based on statistical analysis of workloads), communications, criminalistics, crime prevention, and other areas. A federally sponsored research and development

program for systems analysis, field experimentation, and equipment-system development was proposed, along with a federal office for standards in equipment used by criminal justice agencies.

The emphasis on research extended to recommendations for state-level research agencies and units within larger system units. Public and private funding, as well as coordinated efforts with universities and foundations, were part of a plan that included establishing an independent National Foundation for Criminal Research.

The National Strategy outlined in the concluding chapter of *Challenge* incorporated all the recommendations, and identified local, state, and federal responsibilities and possibilities. Six major areas were identified: state and local planning, education and training of criminal justice personnel, surveys of organization and operations of agencies, developing coordinated national information systems, developing demonstration projects, and scientific and technological research and development. Two additional areas were proposed to facilitate the first six: creating institutes for research and training, and grants-in-aid for operational innovations.

Impact

The work of the commission formed the basis for the Omnibus Crime Control and Safe Streets Act of 1968, which incorporated many of the recommendations into the charter of the Law Enforcement Assistance Administration. Modified over time, the commission's strategy remains the basis for many operations of the Office of Justice Programs, including the National Institute of Justice, the Bureau of Justice Statistics, and the Bureau of Justice Assistance. Some of the commission's recommendations were quickly discarded or rendered obsolete by technological advances: Its suggestion that police call boxes be made available to the public was all but rendered moot by the introduction of the 9-1-1 system in 1968. It galvanized research into other technologies, enhancing radio communications and ultimately delivering the Automated Fingerprint Identification Systems (AFIS) in use across the country. Separate development of the RICO statutes put teeth into the Organized Crime recommendations, and over time, almost all of the training and operational

improvements it suggested were put into practice. The work of the commission laid the groundwork for much of the modern functions and innovations of the criminal justice system.

PRESIDENT'S TASK FORCE ON VICTIMS OF CRIME, 1982

The President's Task Force on Victims of Crime was established in April 1982 by President Ronald Reagan (Executive Order 12360). The purpose of the Task Force was to work with the Cabinet Council on Legal Policy to "conduct a review of national, state and local policies and programs affecting victims of crime." According to the Executive Order, the goal of the Task Force was to produce advice for the President and Attorney General for federal actions that might be taken to "assist and protect victims of crime." In December 1982, the Task Force released its well-known Final Report that served as a guidebook for efforts that would be undertaken and prioritized by federal, state, and local governments seeking to support victims of crime and improve the relationship between victims and the criminal justice system. The President's Task Force on Victims of Crime set out to improve the treatment of victims primarily by changing criminal justice system practices through the use of state and federal legislation.

Activities

Ten members of the President's Task Force were appointed by President Reagan, including attorneys, victims' advocates, and representatives from law enforcement and religious groups. According to the Final Report, the Task Force reviewed the research on victimization, interviewed criminal justice professionals and victims' advocates about the challenges faced by victims of crime, and "most importantly . . . spoke with citizens from around the country whose lives have been altered by crime" (p. ii). It is clear from the Final Report that the focal activities of the Task Force were the series of hearings held in the fall of 1982 in several cities around the country, including Washington, D.C., Boston, San Francisco, Denver, St. Louis, and Houston.

In addition to the hearings, the Task Force surveyed the variety of "Victim/Witness Units" in operation around the country. Some of these units were located in police departments or prosecutor's offices, whereas others were located in social service agencies. The Task Force noted that units that were part of criminal justice agencies tended to have priorities that may not have been consistent with the needs of victims, noting however, that with adequate funding and dedicated personnel, victims' needs could be adequately served in such units as long as the needs of victims were prioritized.

The Task Force argued that the following activities were key to responding adequately to victims of crime: (1) assistance for all victims who report a crime, regardless of arrest outcome; (2) the availability of crisis counseling at the scene of the crime; (3) 24-hour hotline service for victims and witnesses, particularly if threatened; (4) emergency financial assistance for home security, food, and other necessities (e.g., destroyed eyeglasses); (5) referrals to victim compensation programs and assistance with the process; (6) public education about the criminal justice system; (7) prompt return of victims' property; (8) victim notification about case progress at all stages of the criminal justice system; (9) appropriate victim input at all stages of case processing, including bail decisions, continuances, plea bargaining, dismissals, sentencing, and parole hearings; (10) victim input on hearing dates; (11) implementation of an "on-call system" for victims and witnesses; (12) assistance with victims' creditors or employers; (13) transportation to court

for those in need; (14) translator services; (15) secure waiting areas for victims and witnesses at hearings; and (16) counseling and advocates for court appearances.

Recommendations

The Final Report made several recommendations for state and federal legislature, federal action, the criminal justice system, and other organizations. First, to facilitate offender prosecution, the Task Force advised that victims' testimony be admissible in preliminary hearings without the victims' presence and abolishment of the exclusionary rule. Next, to protect crime victims and deter future crimes, the Task Force recommended (1) maintaining the confidentiality of victims' addresses, (2) allowing the public to attend parole hearings, (3) eliminating parole and discretionary sentencing, (4) requiring schools to report all violent offenses on school grounds to the police, (5) increasing the availability of sex offender arrest records, (6) covering the cost of physical examinations of sexual assault victims, and (7) changing the current bail laws to keep dangerous offenders detained. Finally, to facilitate the victim recovery process, the Task Force recommended preserving the confidentiality of statements made during victim counseling sessions and that victims' assistance programs should be established by employers.

The Task Force also proposed that federal funding be provided to assist state level victim compensation programs and to support victim assistance agencies at the federal, state, local, and private level. Additionally, creating a resource center that provided information regarding victim assistance and compensation programs as well as other organizations that benefit victims was recommended. Finally, the Task Force called for additional research to examine the exceptional circumstances surrounding family violence (e.g., feelings of guilt caused by reporting the crime), to evaluate the impact of the unique aspects of the juvenile justice system on victims, and to investigate negligence on the part of parole boards (i.e., improve accountability of parole boards).

The Task Force also made several recommendations to criminal justice agencies that included increased sensitivity toward victims, the restoration of property, and the victims' role in the court processes.

For police departments, prosecutors, and judges, the Task Force recommended training on handling the needs of victims (specifically victims of sexual assault) and the awareness of victim services in the community. It reasoned that this would facilitate the healing process and make victims more likely to cooperate at the investigation and trial phases. Also, recommendations were made that victims be updated regularly during the investigation and trial phases, as well as during parole hearings. The Task Force urged police to investigate threats made on witnesses and victims thoroughly and urged prosecutors to charge defendants who attempt to intimidate victims and witnesses.

The Task Force also discovered that, after victims' property was seized as evidence, victims were unlikely to have it returned to them for months or possibly years as their cases progressed. Therefore, it called on police, prosecutors, and judiciary to ensure that property seized from the victim be returned in a timely manner. In addition, the judiciary was urged to order restitution for all victimizations that resulted in a monetary loss.

The Task Force made several recommendations for observing victims' rights at trial. Prosecutors were called on to ensure that the victims' views are represented in all decisions made by the courts (e.g., bail decisions and plea bargains). Specifically, both judges and prosecutors were urged to keep victims in mind when deciding on continuances and during the sentencing phase. In fact, the Task Force argued that continuances occur less frequently and that new dates be suitable for the victim's schedule. Finally, the Task Force argued for the victims' right to be present during trials and parole hearings.

In addition to criminal justice agencies, the Task Force also recommended that hospital personnel, ministry members, schools, and the mental health community receive victim sensitivity training and be aware of victim-assistance programs. The mental health community was urged to study the psychological effects of victimization, and businesses and creditors were urged to be lenient with crime victims when they are absent from work or unable to make timely payments. The Task Force also recommended that the Bar Association ensure that victims' perspectives and needs are represented along with those of the defendants in all court processes.

Influences on Current Legislation and Services

It is clear that the Task Force made an extensive series of recommendations to governmental and other organizations interested in supporting victims of crime. These recommendations set the political agenda for victims' advocates and continue to influence legislation and services today. Prompted by the recommendations in the report, a series of federal legislation was passed, which included the 1982 Victim Witness Protection Act, the 1983 Victims of Crime Act (VOCA), the 1990 Victims' Rights and Restitution Act, the 1991 Omnibus Crime Bill, the 1994 Violence Against Women Act and various subsequent reauthorizations of these bills. Such legislation worked to ensure that in federal cases, victims can participate in ways that were not allowed in the past, such as providing victim impact statements, obtaining restitution, and being informed of the status of their case. It also prompted state governments to pass their own legislation to achieve the same objectives for most victims whose crimes are violations of state, rather than federal, laws.

Prompted by the recommendations of the Task Force, federal legislation also authorized the 1988 creation of the Office for Victims of Crime (OVC) in the Office of Justice Programs (U.S. Department of Justice) for the purpose of coordinating and providing funds to states for victim assistance and compensation, as well as for offering training and information about programs, services, and legislation related to victims' issues. Funding for OVC grants and services comes from the Crime Victims Fund established by VOCA, which receives monies from the fines, penalties, and forfeited bail bonds of those convicted of federal crimes. In 2004, more than \$800 million was collected for the fund, and approximately 6,100 VOCA awards were provided to public and private nonprofit groups to distribute aid to victims. Subsequent legislation also led to the creation of the Violence Against Women Office, which works to reduce and respond to specific forms of victimization, such as intimate partner violence, sexual assault, and stalking, through financial and technical program assistance.

One of the more controversial recommendations of the Task Force has been the creation of "victims' rights amendments." Although most

states have now adopted some version of a victims' rights amendment, such efforts to amend the U.S. Constitution have not been successful. Although many victims' advocacy groups support such an amendment, some political conservatives and liberals, such as the American Civil Liberties Union (ACLU), have opposed such an amendment. The ACLU objects because it believes that such an amendment would transform the core assumption of "innocent until proven guilty" by allowing victims to influence events prior to a finding of guilt and by allowing victims to interfere with plea-bargaining processes, such as those that offer leniency in exchange for testimony against other defendants. Conservative opposition includes concerns about designating notification or speaking opportunities as "rights" in the constitutional sense of the term. They argue that it is not clear what activities by prosecutors or judges, for example, would constitute a violation of such "rights," who might be charged with a violation of such "rights," or the penalty for violations.

Regardless of the different approaches that might be used to minimize the consequences of victimization, there is no doubt that the President's Task Force on Victims of Crime has had a major influence on the ways in which victims are treated by the U.S. criminal justice system. The Task Force hearings and the issuance of the Final Report served as both a catalyst and as a blueprint for the legislative and policy changes that occurred during the past 25 years, and it is also likely to guide such efforts into the 21st century.

PRISON VIOLENCE

As institutions designed with the expressed purpose of confining law violators, *prisons* (hereafter used to refer to any facility housing both adult and juvenile pretrial or convicted offenders, including correctional institutions, jails, youth detention centers, etc.) confine within a relatively small space a population that has demonstrated an inability to abide by the laws of open society. This population includes many individuals with a history of violent behavior. The different combinations of population characteristics, environmental pressures and stress, inmate-staff relationships, and particular control practices create dynamic environments that can make prisons highly susceptible to outbreaks of varying kinds of violence. Understanding the extent of prison violence, factors associated with its occurrence, and the effectiveness of different mechanisms to reduce such incidents are important issues for policy makers, as well as prison administrators and staff.

The Extent of Prison Violence

Exactly how much violence occurs in contemporary prisons is difficult to determine. Definitional variations, prisoner unwillingness to report victimization, official reporting practices, and the use of staff discretion all raise validity and reliability problems for the limited data that do exist. Furthermore, it is well established that levels of violence differ across prisons and that these levels can vary significantly over time. It is well accepted, however, that

the threat of violence is far more common than actual assaults. For example, anonymous surveys of English prisoners found that 15% to 75% of prisoners (depending on the facility) indicated having been threatened with physical harm during their incarceration. Among those same inmates, as few as 2% and as many as 30% indicated that they had actually been assaulted during their incarceration. Studies of American prisons find similar variation across facilities, although there is some indication that the number of violent incidents may be slightly higher for some American institutions. Evidence of prison homicide indicates that although it does occur, it is not as high as the size and nature of most prison populations might suggest. The homicide rate for American prisoners seems to be higher than other western European countries. However, according to the Bureau of Justice Statistics, the number of homicides within American prisons and jails has remained at or below 100 homicides for several years despite a substantial increase in the size of American prison populations.

Evidence about the extent of sexual attacks is widely divergent, with some studies reporting a relative infrequency of such incidents, whereas others find that sexual attacks are a fairly common feature of prison life. Several characteristics, such as being young, effeminate, physically weak, or White have been reported as individual risk factors for sexual assault in prison. Attacks of a sexual nature have been reported by 3% to 13% of English prisoners and even higher numbers have been reported in some American studies.

Concerns About Prisoner Violence

Researchers and correctional professionals are concerned about several aspects of prison violence. First, there is the distinction between individual and collective violence. In reality, these entities are not mutually exclusive. Violence by an individual prisoner against another prisoner or staff (or staff against prisoner) may lead to more collective violence by groups of prisoners (e.g., prison gangs) against another group. Second, research often distinguishes sexual assaults from other types of physical violence. The Prison Rape Elimination Act of 2003 was passed by the U.S. federal government with the goal of better understanding the extent of sexual assaults within prison and creating more effective strategies

to reduce such incidents. Finally, although the public interest is typically focused on violence committed by inmates against staff or other inmates, several high-profile incidents have also raised attention to the issue of violence by staff against inmates.

There are important reasons to attempt to minimize violence within prison. First, from a legal and moral perspective, convicted offenders are sentenced to prison *as* punishment, not *for* additional punishment. Sentencing individuals, many of whom have been convicted of nonviolent offenses, to prison environments where they are likely to be victims of physical or sexual assaults is inconsistent with any legitimate justification for punishment. A second concern is for the well-being of prison staff who interact with prisoners on a daily basis. Inmates typically outnumber staff by substantial numbers in all but the most secure facilities, and it is understandable that concerns about their personal safety are paramount. Furthermore, the responsibility of breaking up fights between prisoners puts staff at risk for intentional or accidental harm. Third, prison violence interferes with normal prison operations. The primary goal of any correctional facility is maintaining secure custody over the inmates. Without a sufficient degree of control, other institutional functions and goals, such as rehabilitative interventions, cannot take place. Violent incidents may require considerable staff intervention and upset the daily routines that organize and define prison life. Finally, most (more than 90%) prisoners will eventually be released from prison. As prisoners return to the community, it is reasonable to consider how the prison experience will affect their ability to reintegrate into society and maintain a law-abiding lifestyle. Prisoners affected negatively by prison violence may find the transition back to open society more challenging. Community safety and quality of life, the justice system, social service systems, and prisoners' families can suffer as a result of the physical or emotional damage caused by negative prison experiences among released prisoners.

Conceptualizing Prisoner Violence

Many forms of prison violence can be characterized as a result of poor coping or maladaptation to the prison environment. Two major theoretical traditions are found in the research on prisoner

coping. The first, which is often described as an environmental or deprivation perspective, has focused on the role that the prison environment has on prisoner coping. This line of research has examined the impact of common features and deprivations of prison life on prisoner behavior within the institution. Interest in the differential impact of prison architecture, daily routines, prison management styles, and prisoner-staff relations on inmate conduct emphasize the important role that physical and social contexts have on prisoner (and staff) conduct within a prison. For example, research has generally found that higher security prisons experience greater levels of interpersonal violence against staff and other prisoners. This seems self-evident: Security-level placement is based primarily on an assessment of a prisoner's potential for violence and institutional misconduct. Therefore, higher security facilities house more dangerous and incorrigible prisoners. Research, however, has found that not all prisons experience the same levels of violence, even when controlling for security level. Other important environmental features, such as specific prison culture, relations between staff and prisoners, and perceptions about the legitimacy of administrative practices, seem to exert considerable, although perhaps subtle, influence on prisoner conduct.

The second major perspective is often described as the individualistic or the importation model of prisoner coping. This model examines how the different characteristics, skills, and experiences of prisoners are associated with disciplinary or coping problems. The individual attributes and pre-prison histories of prisoners are considered central factors in understanding their likelihood to experience coping problems, such as violence against staff or inmates, self-injury, and emotional distress. This line of research has identified several individual-level attributes that seem to be associated with prisoner violence and poor coping. The most common predictor of interpersonal prison violence is age. Younger prisoners are far more likely to be assailants and victims than older inmates. This is often attributed to the stress of adapting to the prison and the importance of not appearing to be "weak" or susceptible to exploitation from other prisoners. Other individual attributes are more complicated to interpret. For

example, research has found that prisoners with emotional or psychological disorders, those sentenced for violent crimes other than homicide, and those with numerous institutional experiences are more likely to engage in violence and other disruptive behaviors while incarcerated. However, official records of such incidents suffer from reporting errors and may be biased by official responses to and reporting of the conduct of different types of prisoners. This is of particular concern for the finding that minority prisoners are more likely to engage in violence than White prisoners who are more likely to be victimized than Black inmates.

A third, more recent focus has been on understanding the complex interaction between individual prisoner attributes and environmental factors within the institution. In essence, this is the recognition that prisoners with particular characteristics are likely to cope more successfully (i.e., engage in less violence) in prison environments with particular institutional features. Even though this may seem like common sense, it actually poses rather complex research challenges and requires collecting data on prisoners and prison environments in multiple institutional settings. Given the numerous difficulties in collecting meaningful data from prisons, many questions remain unanswered, yet this perspective will likely enhance our understanding of prison violence.

Strategies to Reduce Prison Violence

Perhaps the most common strategy to reduce prison violence is through the use of classification instruments to assess inmate risk (for violence, escape, disruptions, etc.) and place prisoners in appropriate security-level environments. The instruments used to assess risk vary across jurisdictions, but most include measures such as the nature of the offense, conduct during previous confinements, substance abuse and mental health histories, gang affiliation, and other variables thought to be associated with prisoner misconduct. The success of this process depends not only on the specific instrument used to assess risk but also on the resources and different environments available for placement. Research has found that properly designed, validated, and implemented instruments can reduce inmate disciplinary problems, which include violence. Critics, however, point out that the overall effectiveness of classification instruments in reducing prison

violence will likely be limited as long as the environments to which inmates are sent are violence prone.

A more contentious body of research has considered how management styles and administrative regimes can influence levels of violence within a prison. Although a wide variety of leadership and management approaches are available, for the current purpose, it is sufficient to conceptualize these differences based on a continuum that ranges from a strict control model to a more open, participatory model of prison management. In the former model, staff members are discouraged from the use of discretion and prisoners are treated as objects to control with little input into prison practices and routines. At the other end of the continuum are management strategies that allow varying degrees of prisoner input into prison operations and routines and encourage staff to develop positive, but limited, relationships with prisoners in an effort to establish legitimacy and trust. Although it is clear that prison management can greatly affect the quality of life for prisoners and staff, research on the effectiveness of these different approaches is mixed. Some of the discrepancies found in prison research are likely found because individual prisons are affected by forces beyond simple management decisions and styles. At times, these forces have worked in concert with a given management style to produce positive results, whereas at other times, the management style was likely undermined by constraints and pressures beyond the control of institutional leaders.

Toward the end of the 20th century, many newly constructed jails and prisons were designed around the concepts of unit management, "new generation" architecture, and direct supervision models. Although each is a distinct concept, for the current purpose, it is sufficient to point out the common feature of dividing the prison into smaller, more manageable units. Within unit management, groupings of (ideally) less than 250 prisoners are contained within distinct units or wings of the facility and nearly all prison activities are provided within the unit. By creating familiarity between prisoners and staff, more closely monitored supervision within a smaller unit, and more responsive routines, problems are thought to be more easily identified and addressed. The new generation prison designs create smaller housing units or pods

in which prisoners spend most of their time. The units themselves may be more or less restrictive and may incorporate a variety of situational crime-prevention strategies designed to minimize misconduct. Associated with new generation facilities is the concept of direct supervision in which correctional officers are stationed within individual units and have direct contact with inmates. The goal is to increase supervision and help create more normalized relations between staff and inmates. In some high-security units, officers may be stationed behind safety glass but they maintain a relatively constant presence and observation over the unit. Although limited, the research to date suggests that these efforts have met with some success. In particular, when properly implemented, unit management and direct supervision have been found to reduce a variety of misconduct problems.

Finally, the use of prison architecture and management to reduce misconduct has found its most extreme manifestation with the creation of supermax prisons. Often described as a prison within a prison, these facilities are designed to house the most incorrigible and dangerous prisoners. Other than for services that cannot be provided within the cell, inmates are confined to their single-bed cells. Although politically and operationally popular in the United States, considerable controversy surrounds the use of these facilities. In addition to the extreme cost to construct and operate supermax prisons, critics question the long-term impact of the extreme isolation imposed on prisoners. Prisoner-prisoner violence within supermax prisons, however, is greatly reduced by means of isolation. The low inmate-to-staff ratio (often as low as 3:1 compared with as high as 100:1 in less secure facilities) greatly reduces serious injury to staff, although the use of force by staff in these facilities is not uncommon. Research has not found, however, that supermax prisons significantly reduce violence against staff or inmates in other prisons within the prison system. Thus, the purported deterrent value of supermax prisons to reduce misconduct generally across a prison system's population seems to be weak.

PROBATION/PAROLE AND VICTIMS

Probation and parole are responsible for the supervision of more than 5 million adult offenders in the United States. As the most common disposition in the United States for felony convictions, probation is a sentence in lieu of incarceration that monitors people under conditions of release. The two types of probation conditions are mandatory and special. Mandatory conditions are defined by state or federal statutes and apply to every individual sentenced to probation. These conditions generally include not owning or carrying a weapon, reporting to a probation officer on a schedule that is determined by the officer at intake, leaving a jurisdiction only with the judge's knowledge and approval, allowing unannounced home visits by the officer, and remaining free of arrests during the probation period. Special conditions are imposed by the judge during sentencing and apply to the particular circumstances of the case. They can include participation in treatment for alcohol or drug abuse, the payment of fines, the obtaining

of mental health services, and earning a General Equivalency Diploma.

Parole is not a sentence; rather, it is the extension of a prison into the community and under the supervision of the parole authority, which is a branch of the prison system. Prisoners are eligible for parole after they have served a minimum number of years of their sentence as dictated by state statutes and the discretion of the judge. A parole board reviews their crimes, their criminal histories, and their behaviors in prison to decide whether the prisoners can be supervised safely in the community. After serving only a portion of their sentence, prisoners can also be released automatically by the prison administration for good behavior, which involves observing prison rules. In a common formula, prisoners are given 1 day off of the sentence for every day of good behavior. The conditions of parole supervision are set by the releasing body and are similar to the mandatory and special conditions of probation supervision.

Probation and Parole Officer Responsibilities

Statements of Victim Impact

In the preparation of presentence investigation reports, which help judges determine whether probation is an appropriate sentence, probation officers often include a section that describes the impact of the crime on the victim and the victim's family. Similarly, at parole board hearings, victims and their family members can testify regarding the impact of the crime on their lives. In the former, the victim impact statement can influence the judge to choose prison over probation as a more just sentence given the nature and extent of victim harm that was perpetrated in the case. In the latter, the parole board can factor victim harm into its decision and conclude that the prisoner's early release would be unjust in light of the suffering of the victim and the victim's family because of the crime.

The presentence investigation and the probation intake assessment also provide the judge with a basis for setting the special conditions of the sentence. Specifically, the judge can decide that the offender must make amends to the crime victim through the payment of restitution.

Restitution is the act of being ordered to pay for lost, stolen, or damaged property, or for medical bills that were incurred in the treatment of the victim for physical or psychological injuries. Failure to pay restitution to the victim is a violation of probation that can result in a prison sentence or other punishments. Many times, probation officers find it difficult to collect victim restitution because offenders are indigent and struggle to obtain the gainful employment necessary to meet their financial obligations.

Enforcing the Conditions of Supervision

Probation and parole officers are responsible for enforcing the conditions of community supervision. Failure to obey these conditions can result in a violation of probation or parole. The former can result in a longer sentence to probation or stricter conditions of supervision; the latter usually results in a return to prison. In the enforcement of the conditions of probation and parole, officers' duties focus on the rights, needs, and recovery of crime victims.

In cases of victim abuse and interpersonal violence, probation and parole officers participate in ensuring the safety of the victim through the enforcement of orders of protection. Such orders prohibit offenders from having any contact with the victim or being within a certain geographic proximity to the victim. The failure to abide by the orders is corroborated by the officers who use victim reports of offender harassment as evidence to file a petition to have the probation or parole revoked. To help victims cope with injuries or other adverse effects of victimization, probation and parole officers broker services from public or private agencies that respond to the needs of crime victims. They also notify victims about changes in an offender's case status. For example, parole officers can notify victims about a parolee's release date from prison and probation officers can notify them about a violation of probation hearing or when a probation sentence is near termination or completion.

Service Provision

The provision of services to victims by probation officers began in the 1970s on the heels of

the Victims' Rights Movement, which propelled victims' needs into the public and legislative consciousness and underscored the importance of treating crime victims with compassion and sensitivity at every step in the criminal justice process. In many states, probation officers are responsible for providing victims with a copy of the Victims' Bill of Rights, which have been passed throughout the country, and with information about the progress of their case through the court system, as well as the court's expectation regarding their obligation to participate in the proceedings.

In addition, probation officers facilitate victim-offender reconciliation, mediation, and dialog programs, which are critical in the achievement of victim healing and offender rehabilitation. Such programs can be therapeutic to both offenders and victims. Probation officers can educate victims about sentencing practices and the nature of probation, which helps them feel more involved in their cases and more informed about outcomes at each stage in the probation process. Finally, probation officers can refer victims for services to treat their emotional injuries and to help them adjust more effectively in the aftermath of serious criminal victimization.

PROBLEM-ORIENTED POLICING

Problem-oriented policing is a comprehensive framework for improving police service; it was first articulated by law professor Herman Goldstein in 1979. Since then, many police agencies and police research institutions have sought to incorporate its principles and methods into the routine business of policing.

The basic elements of problem-oriented policing are as follows:

1. Police business is understood as clusters of crime or disorder incidents that are similar in one or more ways. These clusters of incidents are referred to as “problems.”
2. Problems are carefully analyzed drawing on the knowledge and skills of crime analysts as well as field personnel.
3. The ultimate purpose of problem analysis is to discover new and more effective responses to problems.
4. Responses that work to prevent crime and disorder incidents, and not merely to react to them after they have occurred, are given high priority.
5. Response strategies that are not entirely dependent on the operations of the criminal justice system are encouraged.
6. Response strategies that engage the community, other public agencies, and the private sector in reducing the problem are emphasized.
7. New response strategies are implemented as fully as possible.
8. The impact that new response strategies have on the problem is evaluated carefully.
9. The results of the analysis, response implementation, and evaluation are reported so that others can benefit from the newly acquired knowledge.
10. The accumulated knowledge gained through this process contributes to the development of a larger body of knowledge that enhances professional policing.

Basic Premises

Problem-oriented policing builds on some basic lessons learned about policing during the past several decades. Among the most critical of those lessons are the following examples.

The function of the police is, and always has been, much broader than merely enforcing criminal laws. Police are expected to address a wide range of community problems that threaten public safety and order. Enforcement of the criminal law, which is often thought to be the basic purpose of the police, is better understood as but one means to achieving the ends of public safety and order.

Police officers exercise a tremendous amount of discretion, at all levels of their hierarchy, in carrying out their function. Problem-oriented policing represents a significant effort to harness and guide that discretion toward more effective and fair policing.

The police, as an institution, operate not merely as the front end of the criminal justice system but as a key institution in a web of social institutions that share responsibility for providing for public safety and order. Problem-oriented policing encourages police to collaborate both within and outside the criminal justice system to address public safety problems.

The police have, for various reasons, been compelled to rely excessively on the criminal justice system as a means for addressing crime and disorder. The overuse and misuse of the criminal law has contributed to major problems in policing. Problem-oriented policing promotes the use of alternatives to arrest as means of addressing problems.

Police have long used formal and informal alternatives to criminal arrest to address problems, but the use of those alternatives has not always been officially sanctioned or even acknowledged. Police officers have long been left to improvise in situations where use of the criminal law is inadequate. Problem-oriented policing stresses the importance of giving formal sanction to legitimate alternative methods of dealing with problems.

The main strategies employed by the police—rapid response to citizen calls for service, criminal investigation, and random preventive patrol—have proven far more limited in their capacity to provide for the public's safety than commonly believed. Consequently, although these strategies remain important aspects of police service, they are insufficient for achieving the entire police mission.

Problem-oriented policing acknowledges the practical limitations of these main strategies while capitalizing on their benefits. It urges police to explore a much wider range of responses to problems beyond the conventional strategies.

Police managers and others who shape police policy and practice have become preoccupied with the administration of police organizations, to the exclusion of focusing on how police organizations can best deliver services to address public safety problems and meet community needs. Problem-oriented policing serves as a corrective to this means-over-ends syndrome.

Line-level police officers, as well as community members, have a reservoir of knowledge, talents, and resources that can be better tapped by police managers for understanding and responding to public safety problems. Problem-oriented policing promotes new styles of working relationships between the police and the public, and between police management and line officers; these relationships can make better use of line officers and community members than conventional police management approaches.

These and other conclusions helped form a much more realistic understanding of the police institution, with all its flaws and limits, than existed before. It was on this foundation of knowledge that problem-oriented policing was built.

Elements

Problem-oriented policing introduces a new basic unit to police work: the problem. In conventional policing, a call for police service, or a case, is the basic unit of police work. Each call and each case is handled separately. Once handled, each call or case is considered closed, and attention turned to the next call or case. Problem-oriented policing looks for patterns among individual calls and cases; these patterns may be formed by a common set of offenders, victims, locations, times, or behaviors. It clusters calls and cases into new basic units known as problems. The enterprise of policing is thereby transformed from one of merely handling individual calls and cases to one of addressing problems.

Some examples of problems commonly faced by police are assaults in and around bars, retail theft in shopping malls, cruising along commercial strips, traffic control during large public gatherings and demonstrations, street prostitution, disorder

at budget motels, speeding in residential areas, homicide among intimate partners, sexual abuse of children, drug dealing on street corners, illicit sexual activity in public parks, loud parties, and street robbery, to name but a few.

These sorts of problems constitute the business of policing. These problems can be experienced and addressed at various levels of aggregation. That is, problems may be experienced at particular locations, at multiple locations throughout a jurisdiction, or across multiple jurisdictions.

To address problems, police must first understand the conditions that contribute to these problems. Developing this understanding requires that police carefully and completely examine and analyze the factors that are contributing to or causing the problems. Doing so requires the police to go beyond merely proving the elements of a crime or filling in the boxes on a standard police incident report. It calls for blending social science research principles with practical police experience to explore such questions as the following:

How big and how serious is the problem? Who is harmed by the problem, and how? How concerned is the community about the problem?

What conditions and factors contribute to the problem? Where does the problem exist, and, conversely, where does it not exist? What explains the difference?

How do police currently handle the problem, and with what effect? Is the current police response helpful or ineffectual, or does it perhaps create more serious problems?

What other groups, organizations, and individuals share responsibility for addressing the problem, and how are they currently addressing the problem? What is the police interest in addressing this problem, and what is the proper role for police in addressing it?

How are similar problems handled elsewhere? What alternatives are there to handling the problem that might improve the current response? Are those alternatives currently feasible, and if not, what needs to be done to make them so?

With new insights into the problems gained from careful problem analysis, police are encouraged to develop new responses to problems; these responses

are tailored to the problem and to the particular conditions of the local setting in which it occurs. Police are encouraged to develop responses, or more typically, combinations of responses, beyond the conventional. They are especially encouraged to consider responses that minimize the need for police to use force, that have community support and engagement, and that have potential to prevent future incidents or minimize the harm caused by them. Alternatives to the conventional responses of arrest and preventive patrol might include the following: pressuring others who control the conditions that give rise to problems to alter those conditions; mediating conflicts; physically redesigning buildings, streets, and other structures; mobilizing the community; conveying information; or using civil laws to regulate problematic conduct or conditions.

Analyzing problems in this fashion has heretofore not been routine for police. To the extent police have analyzed crime problems, it has more typically been with an eye toward predicting the next crime in a series and trying to interrupt it and apprehend the offenders. The sort of problem analysis prescribed by problem-oriented policing goes beyond conventional crime analysis. Thus, the concept will require police to develop a much greater capacity to analyze the problems that constitute their business and a capacity to use that analysis to inform their policies and practices.

A problem-oriented approach to police work requires that police adopt an open posture with respect to their work; that they be willing to critique their own actions, to search actively for ways to improve their responses, and to assess rigorously their efforts to inform additional improvements. It requires a new level of openness and candor with the public and other government officials about what is realistic to expect of the police with respect to various problems. It calls for a new level of engagement by various sectors of the community and the government to assist the police in addressing difficult public safety problems.

The overarching objective of problem-oriented policing is to make police more effective in addressing the wide range of public safety problems they confront routinely. Merely making police more efficient, and even better liked and supported by the public, are subsidiary objectives to the ultimate set of objectives related to keeping society safe and orderly, which is consistent with the principles of a constitutional democracy.

Problem-Solving Processes

Problem-oriented policing makes use of several problem-solving methodologies, which are all rooted in the social scientific method of inquiry. Perhaps the best known problem-solving methodology associated with problem-oriented policing is the one known as the SARA model. SARA is an acronym that stands for *scanning*, *analysis*, *response*, and *assessment*. It was developed by researchers in an early experiment applying problem-oriented policing in Newport News, Virginia, in the 1980s. The SARA model, like other similar problem-solving models, is commonly portrayed as a linear or sequential model—that is, that it flows neatly from beginning to end. In fact, it is an iterative or cyclical model—inquiries lead to some answers and to more inquiries, and all the while the inquiry is underway, police and others may be taking interim action to address the problem. Assessment, or evaluation, of the effort may lead to the development or refinement of responses or to new lines of inquiry.

Each stage of the SARA model calls for the following specific steps to be taken:

Scanning

The scanning phase involves identifying recurring problems of concern to the public and the police, identifying the consequences of the problem for the community and the police, prioritizing those problems, developing broad goals, confirming that the problems exist, determining how frequently the problem occurs and how long it has been taking place, and selecting problems for closer examination.

Analysis

The analysis phase involves identifying and understanding the events and conditions that precede and accompany the problem, identifying relevant data to be collected, researching what is known about the problem type, taking inventory of how the problem is currently addressed as well as the strengths and limitations of the current response, narrowing the scope of the problem as specifically as possible, identifying a variety of resources that may be of assistance in developing a deeper understanding of the problem, and developing a working hypothesis about why the problem is occurring.

Response

The response phase involves brainstorming for new interventions, searching for what other communities with similar problems have done, choosing among the alternative interventions, outlining a response plan and identifying responsible parties, stating the specific objectives for the response plan, and carrying out the planned activities.

Assessment

The assessment phase involves determining whether the plan was implemented (a process evaluation), collecting prerespone and postresponse qualitative and quantitative data, determining whether broad goals and specific objectives were attained, identifying any new strategies needed to augment the original plan, and conducting an ongoing assessment to ensure continued effectiveness.

Relation to Other Police Reform Ideas

Problem-oriented policing shares common features with several other movements in police reform and crime prevention; among these movements are community policing, team policing, and situational crime prevention. It also draws on other conceptual frameworks for analyzing and responding to crime problems, including crime prevention through environmental design (CPTED), crime analysis, the COMPSTAT method, hot spot policing, and crime mapping. Problem-oriented policing rejects, however, the premises underlying such concepts as zero-tolerance policing, because those concepts imply that police discretion will be suspended and that the widespread use of criminal arrest is a viable solution to many public safety problems.

Certain innovations in prosecution and court management run parallel to problem-oriented policing. They recognize that the roles of prosecutors and courts, too, are broader than merely processing cases through the legal system and that public safety problems require changes in the conditions that cause them, as well as a more preventive perspective in addressing them. Concepts such as community prosecution and restorative justice are generally considered compatible with problem-oriented policing.

Implications for the Management of Police Organizations

Full incorporation of the basic elements of problem-oriented policing into the mainstream of policing requires substantial changes in the ways that police organizations are managed and supported. The most profound changes necessary for problem-oriented policing to exploit its full potential are described below.

Developing a New Capacity for Analyzing Police Business

Police organizations, either with internal resources or with assistance from outside research institutions, will need to increase their capacity to organize and analyze information about the demands made on them to improve their responses to public safety problems.

Building a Body of Knowledge About Policing

In contrast to most other professions and trades, police have long lacked an organized, accessible, well-researched body of knowledge about how they should respond to the many public safety problems they confront. Problem-oriented policing represents a commitment to learning what works, under what conditions, and for what kinds of problems. Building this body of knowledge will require contributions from police agencies, research institutions, and government funding agencies. The *Problem-Oriented Guides for Police*, which was produced by the Center for Problem-Oriented Policing with funding from the U.S. Department of Justice's Office of Community Oriented Policing Services, represents one effort to build this sort of body of knowledge.

Training and Educating Police

The shift away from an incident-driven style of policing, in which police merely respond to emergencies, handle calls for service, and investigate crimes, to a problem-oriented style of policing will require that police officials, at all levels of the hierarchy, learn new knowledge and new skills. They will need to learn more about the dynamics that cause the many public safety problems as well as the skills necessary to identify and analyze problems and to manage problem-oriented police operations.

New educational and training methodologies will be in order as well. Problem-based learning methodologies will need to replace conventional police training methodologies.

Supporting Police

For police organizations to become more effective in controlling public safety problems, they will require a different level of support than simple funding for police officers and police equipment. The respective governments under which police organizations exist, and the public at large, must come to view public safety in broader terms; they must view public safety not as the sole province of police but as the joint responsibility of police, other government agencies, nongovernmental organizations, and the various sectors of the community. It will require greater recognition of the interrelationship of crime and such other realms as land use planning, architecture, urban design, civil code regulation, mental health and substance abuse treatment, youth services, product design, and business policies and practices. It will require that the ownership of and responsibility for addressing various public safety problems be negotiated among the various sectors of society, police included, that have stakes and interests in those problems.

Problem-oriented policing implicates nearly every aspect of police management. In addition to the changes described above, it calls for rethinking how police officers are recruited and selected, how police officers' and police agencies' performance is measured, how police agencies are organized and staffed, and how public expectations for police service are managed.

PRODUCT DESIGN: CONCEALABLE, REMOVABLE, AVAILABLE, VALUABLE, ENJOYABLE, AND DISPOSABLE (CRAVED), AND VALUE, INERTIA, VISIBILITY, AND ACCESS (VIVA)

The acronyms CRAVED and VIVA are central components of Ronald Clarke's Situational Crime Prevention (SCP) approach and Marcus Felson's Routine Activities Theory (RAT). Essentially, both RAT and SCP focus more on understanding how crime happens than why people get involved in offending in the first place.

RAT and SCP are constantly evolving to deal with the constant changes and developments in modern society and its technology. The originators of these approaches and their followers develop and refine them constantly to take account of lessons and criticisms. Today, both of these approaches remain mostly, although by no means solely, concerned with tackling proximal issues of crime problems as they manifest in the "here and now" rather than crime's more distal underlying causes. To date, these approaches have not sought to encompass wider areas of criminological concern, such as punishment or treatment of criminality, but we should not always expect it to be that way. After all, to do so would be to embrace fully a

delusion of permanency that would blinker academic foresight in the constantly changing world of crime and criminological efforts to reduce it.

SCP and RAT are approaches to tackling crime problems quickly, to ease the burden of crime on victims rather than looking for long-term social solutions that may take years to impact. In essence, then, SCP and RAT for the most part are concerned with reducing opportunities for crime to occur rather than reducing or changing those things that lead people to be more at risk of becoming, or continuing to be, criminal.

Definitions

When a theft takes place, a victim may be absent at the time of their victimization. From this cause, Felson's RAT prefers to use the term *target* rather than *victim*. According to Felson's earlier work, the four main elements that contribute to a target being at risk of criminal attention can be best understood and remembered by the acronym VIVA:

- Value
- Inertia
- Visibility
- Access

The acronym CRAVED is another heuristic device that enables us to understand what it is about a crime target that puts it at the top of a thieves "shopping list." CRAVED is what makes products hot. They are generally

- Concealable
- Removable
- Available
- Valuable
- Enjoyable
- Disposable

Comparing VIVA with CRAVED, it is plain to see that they deal with identical attributes. *Value* in VIVA is the same as *Valuable* in CRAVED. *Inertia* is the same as *Removable*, and *Visibility* and *Access* are both neatly covered by *Available*. The acronym CRAVED then has surpassed VIVA, and CRAVED has an additional two elements, which more comprehensively cover the characteristics of a target that influences offender motivation.

Historical Perspectives

Clarke's SCP arose in the 1980s from early research he conducted while working at the U.K. Home Office. Seeking to establish why some penal facilities for young people (borstals as they were then known in the United Kingdom) had a significantly higher rate of inmate absconding than others, he found that the only causal factor was the opportunity to escape that was presented by either the physical security of the borstals or elements of the regimes. This finding led Clarke and others to research opportunity as an important way to understand and reduce crime quickly, cost-effectively, and in ways that had minimal social intrusion. As it has developed, SCP today has its roots in a combination of RAT, crime pattern theory, and the crime as rational choice.

A review by Nicholas Tilley in 1993 concluded that in the United Kingdom, crime was unlikely to be reduced significantly by social control initiatives, policies of imprisonment, punitive sentencing, or even preventive policing. Tilley did, however, identify the reduction of criminal opportunities as an area that was worthy of more criminological attention.

SCP essentially employs measures that are directed at specific crime types and forms and seeks to work by means of management, design, or manipulation of the immediate environment to do the following:

- Increase the perceived *effort* of committing the crime
- Increase the *risks* of committing the crime
- Reduce the *rewards* from committing the crime
- Reduce the *opportunities* for crime
- Remove *excuses* for committing the crime

Using classic action research methodology, SCP is based on the following principles:

- Collecting data about nature and dimensions of a specific problem
- Analyzing the situational conditions that permit or facilitate this crime
- Studying systematically the possible means to block opportunities for this crime
- Implementing the most promising, feasible, and economic measures
- Monitoring the results and then disseminating any knowledge

VIVA was first coined by Lawrence Cohen and Marcus Felson in 1979, and it was surpassed by CRAVED, which was invented by Clarke in 1999, as a useful crime reduction acronym to address the characteristics of a target that influences offenders' motivations. The development of the acronym CRAVED to replace VIVA was strongly influenced by Mike Sutton's earlier work on stolen goods markets, which markedly criticized both Clarke and Felson for failing to recognize that trading in stolen goods is an area where opportunity reduction in trading, rather than stealing, can be used to reduce theft by reducing offender motivation. In saying this, Sutton's critical work opens up a whole new avenue for Clarke and Felson—whose writing had until this time taken the existence of *motivated offenders* as an accepted *constant*, which opportunity reduction measures, such as RAT and SCP, could do little to reduce.

It was Sutton's concept of the Market Reduction Approach to Theft (MRA), which explained in detail crime reduction strategies that might work using SCP and RAT to reduce stolen goods markets by tackling offender motivations through reducing opportunities to convert stolen goods into cash or drugs. Therefore, in including *enjoyable* and *disposable* elements in CRAVED, Clarke was seeking to include a target's characteristics that actually motivate offenders to pick it. Clarke and Felson picked up on the newly identified need to address how certain hot products, and the markets for them, actually motivate thieves to steal. Indeed, most notably, the third edition of Felson's *Crime and Everyday Life* carries a picture of a pawnbroker's shop on the front cover, because these are places known to be regular outlets for stolen goods.

What the Acronyms Are Designed to Do and How

Felson used his VIVA acronym alongside his famous three key elements of the chemistry for crime, which include the presence of (1) suitable targets, (2) likely offenders, and (3) an absence of capable guardians.

The aim of VIVA was that it serves as a simple heuristic device—as a tool—for criminologists, police officers, and others seeking to reduce crime to examine things from an offender's point of view both to understand and predict *who does what to*

whom where, when, and why. The ultimate purpose behind designing such acronyms is so that scarce crime-fighting resources can be deployed most effectively where they are most needed and most likely to work to reduce crime.

VIVA works like this. First, thieves generally steal with an aim to sell those stolen goods for cash. This means thieves will steal only those items that they know or believe to have a good cash *value*. Thieves need items that are readily converted into cash at places where they know that they can readily sell them. This is what makes these items *valuable*. Second, in terms of *inertia*, items generally need to be portable. Vehicles may be driven away, but it is unlikely that a domestic burglar will steal a brand-new, top-of-the-line refrigerator because it will be too heavy and large to carry, conceal, and transport. *Visibility* is important because unless a house burglar has been in the home before, for example, he or she will not know for sure that it contains items that have *value*. However, if, for example, a homeowner leaves a laptop computer on the windowsill, it lets the offender know that burglary will secure at least one item he or she can easily carry away, conceal, and sell. *Access* is used to consider immediate vulnerability of targets to criminals. For example, an open window or door on the ground floor provides easy access to criminals. An open window on the 35th floor may not.

As explained above, CRAVED is now used by both Clarke and Felson instead of VIVA because CRAVED was designed to encompass everything that VIVA does and go further by covering offender motivation, which is something that the more limited VIVA does not.

David Mann and Mike Sutton were the first to point out that SCP and RAT would need to examine crime opportunities in cyberspace following the rapid expansion of the Internet in 1998. Accordingly, in 2003, Graeme Newman and Ronald Clarke addressed this issue and adapted the acronym CRAVED to fit e-commerce crimes. Newman and Clarke revealed the remarkable versatility of the acronym CRAVED by showing that it can be used to help us think about how best to understand and address the new problem of hi-tech Internet-facilitated crimes in cyberspace as well as those in the more traditional built environment, as follows.

Concealable: In cyberspace, stolen information, for example, may be transported so quickly that it is never spotted in transit. Then, it can be stashed away so that it is never found. Items such as copyright-protected materials can be stolen by someone operating from another continent as easily as someone from the same town, and many copies can then be made of this information so that it is impossible to tell the original from the “fake.” The Internet then facilitates near-perfect concealment.

Removable: One of the many advantages of the Internet is that information is removable. Consequently, it inadvertently facilitates new ways of stealing. Although passwords and access controls seek to protect information on computers, such as credit card numbers, addresses, and pin numbers, once this information is on the screen of a criminal’s computer, it is, in effect, *removed* as information while never actually going anywhere physically. Having no weight, electronically stored and transported information is ultimately removable so long as the thief has enough storage space at his or her disposal.

Available: The Internet makes available information about how to steal electronic services, synthesize drugs, manufacture bombs, groom children for sexual exploitation, and burgle homes—to name a few examples.

Valuable: Money is, of course, the most liquid and arguably the most valuable of all commodities. Online banking is now commonplace. This means that money in cyberspace is reduced to online “information”—whether that is in the form of a criminally intercepted electronic money transfer or removable banking and credit account details.

Enjoyable: Those who hack into Web sites for political reasons, commit criminal acts, and record them for posting on YouTube, Facebook, blog sites, or Web sites, as well as those who write and spread computer viruses, clearly get a great deal of recreational pleasure from knowing that others—worldwide—view their exploits published on the Internet. Offenders can experience offending on the Internet in many ways as a form of computer game playing. Similarly, information and physical items stolen via Internet facilitated criminal activity

can range from illegal downloads of software, music, and film media, to antiques, or even motor vehicles stolen through eBay auction scams.

Disposable: The availability of outlets for stolen goods on the Internet is demonstrated no better than by the emergence of e-fencing on eBay as a sixth new subtype of stolen goods market to add to the existing five.

CRAVED in Crime and Nature

In his groundbreaking book *Crime and Nature*, Felson revisits the CRAVED acronym from the point of view of looking for similarities between the way offenders and organisms in nature exploit particular niches. This is not as peculiar as it may first appear, because Felson makes reasoned arguments regarding how we can learn from nature's adaptations to a changing world, how we can gain much from understanding the relationships between predators and their prey, and how vulnerable species adapt efficacious defense strategies in ongoing battles for survival.

Somewhat amusingly, Felson tells us that squirrels steal food from his bird feeder and that squirrels also prefer food that is *concealable*, *removable*, *available*, *valuable*, *enjoyable*, and *disposable*, which is why they enjoy eating the food that humans put out for the birds. Taking this analogy forward, Clarke explains how we can effectively reduce crime by (1) increasing the risks for the offender, (2) increasing the effort involved in committing the crime, and (3) decreasing the immediate rewards that come from committing the offense. In an effort to explain, in a humorous and therefore particularly memorable way, the universality of this approach to solve many social problems, Felson points out that the same approach worked to thwart food-raiding squirrels in his garden: "A new bird feeding device increased squirrel risks and difficulties, while decreasing the payoff per raid. Amateur squirrels no longer steal from me, and professionals get less. This is a good example of crime policy intellectuals call 'harm reduction'" (p. 265).

In the third edition of *Crime and Everyday Life*, Felson explains that the CRAVED model can be applied not only to theft targets but also to targets of violence, because violent offenders often seek to *conceal* their crime, *remove* themselves from the

scene of the attack, and sometimes remove the body of their victim, be it alive or dead. Felson goes on to explain that human victims need to be *available* for attacking as well as being *valuable* targets in the violent offender's eyes. The offender may *enjoy* the act of violence and then seek to *dispose* of any incriminating evidence, such as weapons, clothing, or victims.

Of course, the CRAVED model might be applied to cover other crimes besides violence and theft. Street-level prostitution is just another example. The CRAVED model scripts used by punters (customers) are likely to contrast markedly with those of so-called working girls and differ even more perhaps to the way that the CRAVED model might apply to their pimps. The punter driving or walking around a red-light area needs to *conceal* himself from the eyes of the law and may need to *remove* himself from the scene of the initial pick-up to engage in sex and then remove himself once again from that scene once the act is over. The working girl must be *available* and skilled/attractive enough to be *valuable* in his eyes to pay her and risk detection by authorities. Presumably, the whole encounter must be *enjoyable* enough to take the risks involved. Perhaps a key point is that once the act is over, the prostitute is socially and emotionally *disposable*. Trafficking in people, artifacts, drugs, or endangered species is another area where the CRAVED model is likely to be useful. These areas are most certainly worthy of additional criminological endeavor.

Conclusion

Examining crime problems using the early acronym VIVA and the improved model CRAVED helps assess by which mechanism crime reduction measures are likely to be effective. This technique is important in crime reduction. For example, invisible property marketing—using various methods—is a favorite way that many police forces spend crime reduction resources. Yet, research by criminologists such as Knutson and Sutton has shown that property marking has never been proven to work because thieves still steal it, the public buys it, and the police rarely intercept it. Using lateral thinking skills and CRAVED, we might tellingly ask, What is it exactly about invisible property marking that will stop an offender

from CRAVEing any particular hot product? If no satisfactory answer can be found, then scarce crime reduction resources can be deployed in other areas where they are likely to be effective.

As a heuristic device, then, CRAVED is an essential tool not only for helping understand why crimes occur when they do and where they do but also to design and to test new and old approaches to reducing crimes: VIVA CRAVED!

PROJECT PATHE

Project PATHE (Positive Action Through Holistic Education) was a comprehensive school-based program that combined services to students who are identified to be at elevated risk for developing problem behaviors with school-wide organizational changes intended to create a supportive school environment. It was implemented between 1980 and 1983 by the Charleston County School District in Charleston, South Carolina, with funds provided through the Office of Juvenile Justice and Delinquency Prevention's Alternative Education Initiative.

PATHE was guided by a theory of local initiation and program development. It assumed that teacher and school staff participation in the process of change would improve the quality of program implementation and that local adaptation is a necessary part of the implementation process. These ideas were the basis for the team structure and high level of staff participation in decision making that were central to the program.

The focus on school environment was based on the belief that a comprehensive, integrated approach to promoting positive youth behavior is preferable to a more fragmented approach. Even the best designed and implemented violence prevention curriculum, for example, will be of limited utility in the context of a school environment that ignores, or in subtle ways condones, acts of violence. PATHE involved school staff in collaborative planning to design and carry out a constellation of program activities and to refine these activities over time.

Program Objectives and Elements

The educators who initially designed the program collaborated with university researchers in an organization development (OD) activity over the course of the 3-year project that was intended to clarify the program's goals and underlying theory,

target program activities more directly at the intervening theoretical variables of interests, specify program quality standards, and improve the quality of implementation using data feedback. This OD activity followed the Program Development Evaluation Method, which is a highly collaborative method that called for ongoing local team meetings as well as frequent communication between local project managers and the research staff. This activity encouraged local educators to articulate *their own* theory about the causes of the problem(s) they sought to ameliorate. This local theory became the basis for the specific program objectives adopted for the program. In the original implementation of PATHE, the local theory closely resembled social control theory, in which increased attachment to prosocial others, commitments to socially appropriate goals, and involvement in conventional activities prevent youths from engaging in delinquent behavior because they provide a stake in conformity by giving youths something to lose by misbehaving. Project PATHE sought to reduce delinquent behavior and increase educational attainment by increasing social bonding, improving student self-concepts, and decreasing academic failure experiences.

The PATHE program consisted of several major components which were implemented throughout the school year. These components were as follows:

- *Team structure for managing school improvement.* An organizational structure was created to facilitate shared decision making among community agencies, students, teachers, school administrators, and parents in planning for school improvement. The project provided training in assessing needs, researching problems, designing objectives, and implementing plans, with two full-time staff members coordinating the teams.
- *Policy review and revision.* Staff members were involved in revising and improving the curriculum and discipline practices. Activities included an assessment of achievement test results, training on more innovative teaching techniques, supplementary instructional materials, a curriculum guide, in-service training on classroom management, the development of school and classroom rules, and a standard discipline referral procedure.

- *School-wide academic innovations.* Program specialists worked with teachers to develop and implement study skills units for their classes and to encourage them to use standardized achievement test formats when testing students. A free period was also set aside for leading with everyone encouraged to participate.
- *School-wide climate innovations.* Various activities were organized, including a school pride campaign, expanded extracurricular programs, and peer counseling or rap sessions for students to discuss topics of concern.
- *Career-oriented interventions.* A career exploration program was co-sponsored with a local technical college to introduce students to technical careers, and a job-seeking skills program provided students with skills training for finding and keeping a job.
- *Services to target students.* This component targeted 100 high-risk students in each school by helping them define behavioral and academic objectives, providing them with academic and counseling services, and monitoring frequently their progress toward their objectives.

Importantly, although a replication of PATHE would maintain the structure and processes of the original program, the specific activities included in each component would be developed locally, based on local needs and resources.

Evaluation

The evaluation of the original PATHE project compared change on an array of measures from the baseline year to the end of the first year (for four high schools) and second year (for five middle schools) of the intervention. One school at each level was a comparison school selected from among the nonparticipating schools to match the treatment schools as closely as possible. The students in the participating high schools reported significantly less delinquent behavior and drug use, had fewer suspensions, and had fewer school punishments after the first year of the program. Students in the comparison high school did not change significantly on these outcomes. A similar pattern was observed for the middle schools after 2 years. As serious delinquency increased significantly in the comparison school; it decreased (nonsignificantly)

in the program middle schools. Suspensions also declined significantly in the program middle schools, but a similar decline was observed in the comparison school. Several indicators of the school climate directly targeted by the program (e.g., safety, staff morale, clarity of school rules, and effectiveness of the school administration) also increased in the program schools. The target student component was evaluated using an experimental design that compared targeted students with a comparison group of similar students who had not received program services. The program failed to reduce delinquent behavior among target students, but it did reduce dropout rates and grade retention. Graduation rates and standardized achievement test scores also improved for these students.

PROJECT SAFE NEIGHBORHOODS

Project Safe Neighborhoods (PSN) is a major federal collaborative initiative to reduce gun violence. PSN is coordinated by the United States Department of Justice (USDOJ) and is implemented at the local and district level by U.S. Attorneys, who coordinate the efforts of a variety of local, state, and federal agents and officers. The

objective of PSN is to develop, implement, and evaluate data-driven violence reduction strategies in the community and improve the long-term prevention of firearm-related violence. PSN expands on strategies used in Boston, Massachusetts, with Operation Ceasefire; in Richmond, Virginia, with Project Exile; and the USDOJ's Strategic Approaches to Community Safety Initiative (SACSI).

Operation Ceasefire (also known as the Boston Gun Project) was a collaborative effort among Harvard's Kennedy School of Government; the Boston Police Department; the state departments of probation and parole; the USDOJ Bureau of Alcohol, Tobacco, Firearms, and Explosives (ATF); and the local U.S. Attorney's office; among others, that started in 1995. Operation Ceasefire applied a problem-oriented policing approach with a focus on specific crime hot spots. Particular attention was placed on illicit gun trafficking and gang violence. Project Exile was started in 1997, based on coordinated efforts of Richmond law enforcement and the U.S. Attorney's office to prosecute all felon-in-possession, drugs-gun, and domestic violence gun cases in federal court. Project Exile was designed to address the gang violence that had long plagued Richmond. At the time of its inception, the level of murders and shootings had regularly increased each year, with Richmond ranking in the top five murder-per-capita rates in the United States. The SACSI was a USDOJ pilot project that placed a strong emphasis on partnerships, knowledge-driven decision making, and ongoing strategic assessment. SACSI built on the existing foundation created by Operation Ceasefire in Boston. The SACSI project was implemented in five cities—Indianapolis, Indiana; Memphis, Tennessee; New Haven, Connecticut; Portland, Oregon; and Winston-Salem, North Carolina.

Typical PSN initiatives involve U.S. Attorneys working with local law enforcement and other local officials to design a strategy that fits the local problem. Criminals who use guns in the district can be prosecuted under federal, state, or local laws, depending on which jurisdiction can provide the most appropriate punishment. Local PSN groups also design and implement deterrence and prevention efforts using community outreach and media campaigns as well as ensure that local law enforcement and prosecutors receive the training necessary to make the PSN program work.

The Problem

Nearly half a million people are victims of crime involving firearms each year. Despite progress in the fight against gun crime in America, gun crime rates continue to be among the highest in the industrialized world. Since the 1990s, significant declines have occurred in the rate of most types of crime in the United States. Despite these declines, the level of gun crime in the United States remains higher than levels in other western democracies. In 2001, the Bush Administration made reducing gun crime one of the top priorities of the USDOJ, along with combating terrorism and enhancing homeland security.

The Strategy

PSN uses every available means to create safer neighborhoods, by coordinating federal, state, and local law enforcement, and by emphasizing tactical intelligence gathering, more aggressive prosecutions, and enhanced accountability through performance measures. Much of the PSN strategy is delivered in school-based prevention programs to reduce youth demand for guns, in facilitating the acquisition of gun locks for gun owners, by improving background checks for prospective gun sales, and by providing services to conduct crime-gun tracing activities. To ensure the appropriate application of PSN resources, each district U.S. Attorney's Office has a designated PSN contact, who serves as the local coordinator and helps facilitate communication about the program. PSN does not use a "one-size-fits-all" approach. Instead, the program elements are tailored to the needs of each individual district and the local gun crime problem. These PSN programs are often used to supplement and not supplant effective programs that are already in place. Key aspects of federal law related to PSN include brandishing, displaying, carrying, or possessing a firearm in a way designed to carry out a drug-trafficking crime or a federal crime of violence; stealing guns or having anything to do with stolen guns; possessing or discharging a firearm in a school zone, or giving or selling a handgun or ammunition to someone under age 18; obliterating or altering the manufacturer's serial number on a firearm, or transporting or possessing such a firearm; and making or possessing a machine gun, sawed-off shotgun or rifle, silencer, or destructive device without a registration. Five

elements are required for a successful gun crime reduction strategy: (1) partnerships, (2) strategic planning, (3) training, (4) community outreach and public awareness, and (5) accountability.

Partnerships

The USDOJ deploys PSN with a diverse set of organizational partners, including its own ATF and Office of Community Oriented Policing Services, the Academy for Educational Development, the American Probation and Parole Association, American University, the Council of State Governments Justice Center, the Institute for Law and Justice, the International Association of Chiefs of Police, the School of Criminal Justice at Michigan State University, the National Crime Prevention Council, the National District Attorneys Association, the National Gang Center, and the Regional Information Sharing Systems. U.S. Attorneys work with local law enforcement to provide a collaborative, comprehensive, and uniform approach to reduce gun crime. Each U.S. Attorney leads the local task force of federal, state, and local prosecutors and law enforcement, researchers, media and outreach specialists, and community leaders. Members of the local task force work together to implement strategies of prevention, deterrence, and prosecution designed to stop offenders from using guns to terrorize our nation's communities. Examples of these partnerships include the following:

- Gang Crime Investigation and Suppression programs that target those who commit gang-related crimes
- Prevention and Education programs such as Gang Resistance Education and Training (G.R.E.A.T.)
- Data Sharing and Gathering programs that enhance the development of gang databases and studies of gangs and gang activity

Strategic Planning

The strategy for local plans depends on the causes of gun crime, availability of law enforcement resources, and outcomes expected. The specific approach will vary from district to district, although each incorporates the three national priorities.

Those priorities are as follows:

- Increased prosecution of violent organizations by aggressively using federal conspiracy, racketeering, narcotics, and all other available laws to attack and punish violent drug traffickers, violent street gangs, and violent robbery rings
- Heightened enforcement of all federal laws against illegal gun traffickers, and the corrupt federal firearms licensees that supply them, with an emphasis on those gun traffickers who supply illegal firearms to violent organizations and to juveniles
- Renewed aggressive enforcement of federal firearms laws against those persons prohibited from possessing firearms or who use firearms to advance illegal activities, including those persons denied under the Brady Act

Although the local strategic plans should reflect the national priorities, the individualized district plans are more likely to represent the unique challenges of the district. The primary goal of each plan is the same—to reduce the levels of gun crime—but the solutions for the goals will depend on the problems that face each district. Traditional criminal justice interventions, as well as education, life skills training, and substance abuse treatment, can be used in these gun violence prevention strategies. Because of these strategies, individuals more at risk for committing gun-related violent crimes (e.g., probationers, parolees, marginal students, and the unemployed) can lead lives free of violence and substance abuse.

Training

As a part of PSN, several partnering organizations conduct innovative regional specialized training for participants to keep current on trends that affect law enforcement. The incorporation of the training element in the core PSN strategy demonstrates the importance of ensuring that each individual involved in the effort to reduce gun crime has the skills necessary to be effective. This training involves prosecutors, agents, and officers involved in gun crime cases. Training partners include the International Association of Chiefs of Police, the National District Attorneys Association, Michigan State University, American University, the Institute

for Law and Justice, the Academy for Educational Development, the American Probation and Parole Association, the Community Policing Consortium, and the National Crime Prevention Council. Through these national partnerships, PSN offers training and technical assistance to PSN task forces across the country. This training includes issues like firearms identification, firearms safety, federal and state firearms statutes, federal and state search and seizure laws, crime scene and evidence management, firearms trafficking and tracing, and strategic planning.

Outreach

PSN activities focus on community outreach and public awareness, as these components are essential to any successful gun crime reduction plan. U.S. Attorneys organize a team effort to convey the priorities, message, and results of the PSN effort to the media and community members, to help shape the attitudes of law-abiding citizens and those who would otherwise violate gun laws. Outreach activities include producing and distributing literature, conducting mail campaigns, sponsoring local workshops, and producing public service announcements, crime-prevention toolkits, and news articles.

Accountability

A careful and consistent review of gun crime reduction efforts is conducted to ensure an effective and proactive gun crime reduction strategy, both at the local and national level. U.S. Attorneys report to the USDOJ every 6 months on the status of their PSN strategy. These reports include a full description of the gun crime problems in each district and the strategies the local PSN coalition is employing in response. These reports are reviewed by a team that comprises individuals with expertise in each of the five PSN elements. Feedback is provided, identifying model programs to share with other jurisdictions, and providing assistance to districts encountering difficulties implementing particular elements of the PSN initiative.

The Results

As a result of PSN initiatives, federal firearms prosecutions increased 73% from FY 2000 to FY

2005, with an increase in federal gun prosecutions in every federal district. In FY 2005, the USDOJ filed 10,841 federal firearms cases. In FY 2005, the USDOJ prosecuted a record number of 13,062 defendants for violations of federal gun crimes, which represents an increase of more than 62% from FY 2000 figures. In FY 2005, more than 93% of defendants charged with federal firearms offenses were sentenced to prison for convictions on firearms charges or other offenses. Approximately 68% of these offenders were sentenced to prison terms greater than 3 years for convictions on firearms charges or other offenses.

The violent crime rate is at its lowest level since 1973, when the USDOJ's Bureau of Justice Statistics started to collect criminal victimization data. The violent crime rate has steadily declined during the Bush administration, and from 2001 to 2004, it was on average nearly 33% lower than in the preceding 4 years. As a result, nonfatal gun crimes were at the lowest level recorded and were down 42% since 2000. The per capita number of nonfatal violent crimes involving firearms has steadily decreased during the Bush administration, and from 2001 to 2004, it was on average about 36% lower than in the preceding 4 years. In 2004, there were 117,520 fewer victims of nonfatal violent crimes than there were in 2003, and 201,840 fewer than there were in 2000. Every federal district seems to have experienced an increase in collaboration and planning among local, state, and federal law enforcement agencies.

In 2008, over \$13 million was awarded to district PSN initiatives, with amounts ranging from \$64,000 to \$582,000. These awards did not include awards under a separate, but related, Comprehensive Anti-Gang Initiative (AGI). The AGI funds provide support for new and expanded anti-gang prevention and enforcement efforts under the PSN initiative. The AGI funds were designed to enhance task force efforts to combat gangs by building on effective PSN strategies and partnerships. To qualify for AGI funds, the PSN districts must show how their gang funding impacts their PSN strategies and demonstrate their need for additional funding.

PROMOTING ALTERNATIVE THINKING STRATEGIES (PATHS)

Teaching students how to handle conflict and make proper choices when faced with difficult situations (such as peer pressure to use drugs or commit a crime) is a popular intervention that is a part of many different programs and interventions. A key concern is to teach youths how to handle acceptably social and emotional situations that they encounter both in school and throughout their lives. Problem solving and conflict management are an important component of many programs that are commonly taught in schools. Typical programs can have a variety of names, including dispute resolution, dispute mediation, conflict resolution, conflict management, and others. The basic goal of these programs is to avoid and/or resolve conflicts before they escalate into serious problems (such as physical confrontations). School programs typically include a strong teaching component in which kids learn that conflict is natural and that it can be managed through various processes.

Many programs jump directly to the teaching of conflict management tools without addressing a range of underlying issues involved in conflict situations. Among those basic issues are self-esteem, self-control,

relationships, and emotions. The effectiveness of any intervention will be enhanced if those underlying problems are addressed. One noteworthy program for addressing these concerns is the Promoting Alternative THinking Strategies (PATHS) curriculum. The PATHS program has been identified as 1 of 10 programs proven to be effective at reducing violence and preventing crime. This entry examines the PATHS program.

Framework

The PATHS program was initiated in the early 1980s. It is intended to be taught during a 5-year period in elementary school (grades K–5) by the normal classroom teacher. A total of 131 lessons are taught in various units, including readiness and self-control, feelings and relationships, and interpersonal cognitive problem-solving. These units incorporate materials on self-control, emotions, self-esteem, relationships, and solving problems in interpersonal relationships. In essence, the PATHS program targets known risk and protective factors related to conflict and violence, which include impulsivity, emotional awareness, empathy, and problem-solving abilities. The curriculum is typically taught in classes three times a week for roughly one-half hour per session.

Underlying the PATHS program is several theoretical/conceptual models. Each target factor is related to the development of appropriate emotional and behavioral responses in children. These models are as follows:

1. Affective-Behavioral-Cognitive-Dynamic Model of Development—focuses on affect, emotion, cognition, and language, which are needed for appropriate behavioral responses
2. Eco-Behavioral Systems Model—a recognition that it is important to couple educating youths with making environmental changes that support changes in youthful behavior
3. Brain Development—uses the knowledge of neurobiology to help identify problem feelings and methods for training youths to recognize their feelings and what to do about them
4. Psychodynamic Education—based on developmental theory and seeks to develop internal self-control and decision-making skills
5. Emotional Awareness—promotes awareness of one's emotions, feelings, and opinions as they surface in different situations and settings

Each perspective informs the various lessons used in the PATHS program, with the belief that one can improve the social and emotional competence of children in elementary school. An important consideration of the program is that it addresses the school atmosphere as well as the individual needs of each youth. That is, the program requires that changes be made to the classroom atmosphere so that it supports positive peer interaction and social development.

The PATHS curriculum is divided into several units that are taught at various points in the elementary grades. The point at which each lesson is offered is determined by the developmental level of typical youths. Basic feelings, such as happy, sad, mad, and love, are introduced as early as kindergarten, whereas more advance feelings, such as embarrassment, jealousy, and forgiveness, do not appear until sometime in grades 2 to 4. The discussion of relationships begins in 2nd grade and culminates in grade 5, whereas the teaching of formal problem-solving skills does not occur until 4th grade. Throughout the program, it emphasized that the programs offer material that is developmentally appropriate for the children.

Evaluation

PATHS has undergone several evaluations that use experimental and control groups of regular students, as well as special needs students, and the results have been subjected to extensive review by outside experts. Based on the evaluations and the review, PATHS was identified as a blueprint for violence prevention.

Evaluations of PATHS uncover a wide range of positive outcomes. Children who participate in the program show an increased ability to recognize and understand their emotions, can better recognize interpersonal problems, and can identify and use alternative responses to problem situations. Of particular importance is the ability of program participants to avoid the use of aggressive or violent responses to conflict situations. Using follow-up periods of as little as 1 year, evaluations consistently reveal improved problem-solving ability,

increased planning activity, reduced self-reported conduct problems, reduced anxiety, and reduced teacher reports of conduct problems. Participants also display an enhanced ability to express their feelings, identify the feelings of others, and change their own feelings. Interestingly, many positive results are based on a single year of program exposure, as opposed to the intended 5-year program. Greenberg and Kusche also note that PATHS can be adopted for use with different populations, including special needs students (such as the deaf, those with learning disabilities, gifted, and emotionally disturbed youths), and for implementation outside the school setting.

PROPERTY MARKING/OPERATION IDENTIFICATION

The practice of property marking, or as it is known in the United States, Operation Identification (OI), is based on the long-established belief that branding or labeling property with a personal symbol will in some way protect it from theft or ensure its return should it be lost or stolen. There are several reasons for encouraging the marking of property in this way: First, it is intended as a deterrent to burglary; second, it is intended to increase the recovery and return of stolen property; third, it is intended to make it more difficult to dispose of

stolen goods; and finally, it is assumed to increase the detection of offenders or their successful prosecution. Operation Identification thus offers the possibility of preventing crime and reducing victimization.

Development

Marking property to signify ownership has a long history. Branding cattle, for example, has its roots in Ancient Egypt and is still widely practiced today, although the branding options have developed from a crude branding iron to embedded radio frequency identification (RFID) chips. In the 1970s, the notion of marking property as a crime-prevention technique was significantly expanded to encourage the general public to mark many disposable (often electric) goods in their possession. In the United Kingdom, the development was facilitated by the introduction of the post code, this in combination with the house or apartment number, it gives a unique identifier for each dwelling. Of course, this system was not introduced for crime-prevention purposes; it was intended to facilitate the delivery of the mail. It happened that its ability to identify uniquely each dwelling in the United Kingdom meant that marking property with the post code could be used to indicate ownership. In the United States, the driver's license number and state identifier are typically used. The important point is that there needs to be a mechanism through which the property can be uniquely linked to the owner.

The police encourage the marking of any property that might be considered attractive to a thief—radios, televisions, video equipment, small tools, and so on. Property can be marked with an ultraviolet pen, which is invisible in natural light but shows clearly under an ultraviolet light or it can be engraved or stamped. Valuable items such as jewelry or antiques can be photographed (against a ruler to indicate their size) if marking is considered likely to affect their value. Citizens are encouraged to make a list of their marked property and to place a decal or sticker on doors or windows to indicate that property in their home has been marked. It is also important that the police undertake to inspect property recovered from burglaries for signs of marking and to return the goods to their owners.

Effectiveness

There have not been many rigorous evaluations of these schemes, and those schemes that have been examined are now somewhat out of date. In 1975, Nelson Heller reported on a nationwide study across the United States of a range of OI projects and concluded that participants had significantly lower burglary rates after joining than before; cities with OI schemes did not have lower rates city wide; the presence of marking did not significantly hamper the disposal of stolen goods; there was no evidence to suggest an increase in either the apprehension or conviction of burglars; and there was no evidence that OI marking increased either the recovery or return of stolen property.

Since then, more research has largely supported the conclusions drawn by Heller, although there is some debate as to whether individuals are at reduced risk of burglary when they mark their property, and if so, why that might be. Johannes Knutsson, for example, carried out a substantial study in Sweden covering a residential area about 20 miles from Stockholm. During a 4-year period, participation rose from around 13% to 30%, which made evaluation difficult, but Knutsson concluded that the program had not reduced the rate of burglary, even for those who participated in the scheme.

Gloria Laycock carried out a rather different type of evaluation of property marking in a residential area in South Wales. Her evaluation showed in the first year follow-up that domestic burglary was reduced for those participating in the scheme. In common with other studies, there was no evidence of increased recovery of stolen goods as a consequence of OI. Particular effort was made to ensure a high take-up rate among the residents in the target area. This effort took the form of intensive publicity prior to the launch of the scheme. In a second year follow-up, it was found that the burglary rate dropped even more, which was both unexpected and counterintuitive. Further investigation suggested that the reduction was not caused by the marking of property per se but more likely by the considerable attendant publicity. The high take-up had been dependent on the initial publicity, and the reduction in burglary in the first year follow-up led to a great deal of local publicity when the research results were published. This led to reductions in the second year of follow-up.

Laycock concluded that the mechanism through which the reductions were achieved was almost certainly the result of offenders perceiving an increased risk as a consequence of the widespread publicity rather than any effect of property marking itself. It is important, therefore, when evaluating such schemes to be sure of the underlying mechanism through which the initiative might be expected to achieve the expected effect.

In their meta-analysis of what works, what does not, and what is promising, Lawrence Sherman and colleagues concluded in relation to property marking that the crime-reduction effect was not proven. This was on the basis of their reviews of the then-existing evaluation literature, but bearing in mind that many burglaries result in a loss of cash or items that are difficult to mark, it is implausible that OI could have a major effect on reducing burglary. It may, however, be useful when stolen property is occasionally recovered by the police, as it can more reliably be returned to the owner.

PROSPECTIVE CRIME MAPPING

Crime mapping is commonplace in many police forces. It can inform the crime reduction enterprise in at least two ways, as follows:

1. The identification of time-stable “hot spots”—that, when supported with relevant analyses,

can provide an indication of why such areas are criminogenic and how to deal with them. Strategies informed by such analysis may be relatively long term and can involve a range of crime-reduction partners.

2. The identification of where crimes are most likely to occur in the next few days—such analysis is more likely to influence tactical decisions on a daily basis, informing when and where police patrols or other re-deployable resources are allocated.

In this entry, the *prospective crime mapping* approach to the second type of task is considered. The entry is structured in the following way. First, current knowledge about spatiotemporal patterns of crime is discussed. Two theories that aim to explain the patterns and how they should inform crime forecasting are then detailed. This is followed by a consideration of how conventional and prospective hot spot maps are produced and how accurate the different methods are at forecasting future crime locations. Finally, practical issues regarding the use of predictive mapping in a policing context are discussed. Prospective mapping has only been tested for burglary, and consequently the discussion generally focuses on this type of crime. However, the theory and empirical research that inform prospective mapping apply to a range of crime types, and so the relevant types of crime are discussed.

Spatial and Temporal Patterns of Crime

Research demonstrates that crime is geographically concentrated; some places experience a higher volume of crime than others, but the pattern does not stop there. Work concerned with repeat victimization typically shows that within areas of high crime, a few people, facilities, or households suffer a disproportionate amount of the problem.

To some extent, there is stability to where crime is most likely to occur, but there is also a flux to crime patterns. For instance, consider repeat burglary victimization; burglary risk increases as function of the number of crimes experienced, but most repeats occur swiftly and the probability of additional occurrences decays over time.

This type of pattern also occurs at the neighborhood level. For example, when a home is burgled,

a car broken into, or even a person shot, other offenses of the same type occur quickly nearby more than would be expected on a chance basis. Crime clusters in space *and* time. Moreover, it seems that for burglary at least, when crimes occur at the same home or nearby within a short period of time, they are more likely to occur during the same period of the day as each other and on the same side of the street.

Explanations for the Patterns

At least two processes could explain the patterns described. First, it is known that some types of places, people, facilities, and households are more vulnerable to crime than others. Consequently, crime clusters in space. However, it is hard to determine how such a theory of *risk heterogeneity* could explain why crime clusters in space *and* time, rather than just space.

A complementary explanation for the observed patterns concerns offender targeting or foraging strategies. The theory is that having committed crime at one location, an offender increases his awareness of it and the local conditions. Assuming that offenders make at least partly rationale decisions some of the time, such knowledge should inform subsequent targeting choices. For example, an offender who successfully burgles a home with ease is likely to want to repeat the experience. Repeating the experience may be as simple as returning to burgled homes. However, because propinquity and similarity are associated, a similar experience may be had from targeting nearby homes. As things change over time, a swift return would reduce uncertainty. In line with this, analyses of burglaries detected by the police demonstrate that offenders frequently return to homes successfully victimized in the past—and those nearby—shortly after an earlier offense.

On the basis of these findings, it would seem that the risk of crime in an area is the function of at least two things: time-stable factors that signal target attractiveness, and the more dynamic influence of offender foraging activity. Depending on the aim of the analysis, approaches to crime forecasting should take account both influences to differing degrees. Where forecasts are intended to inform short-term tactical decisions, the dynamic element will be of considerable importance. To provide a

context within which to discuss prospective crime mapping, in the next section other methods of crime hot spot mapping are first discussed.

Types of Crime Hot Spot Mapping

Many crime hot-spotting techniques are routinely used in crime analysis, but the overall aim—to identify those areas that *have* experienced the most crime—is the same. Thematic mapping involves counting how much crime occurred within a set of predefined areas, such as police beats. Acknowledged problems with this approach include the Modifiable Areal Unit Problem and the ecological fallacy.

Considering the former, the problem is that the use of different boundaries may generate different results. Apropos the latter, because analyses are conducted at the area level, it is easy to assume that all locations within areas are exposed to the same risks. Rarely will this be the case. Thus, whereas thematic mapping is easy to do and understand, it is insensitive to the precise distribution of risk, and maps so derived can be misleading.

A different approach that addresses these concerns is kernel density estimation (KDE). KDE maps can be generated in a variety of ways, but the following is illustrative:

1. A two-dimensional grid with regular-sized cells is overlaid on the study area. The smaller the cells, the higher the resolution of the map.
2. For each cell in the grid, all crimes that occurred within a particular radius of the cell centroid are identified. A smoothing function is then used to compute an estimate of risk intensity. Simply put, cells that have the most crime within or nearby will have the highest intensity values.
3. Cells are then shaded to reflect the intensity values derived.

Although this approach addresses the problems discussed, criticisms exist. First, the choice of radius used affects the results produced—the larger the radius, the smoother and less sensitive the map—and yet the radius selected is often arbitrary, determined by aesthetic rather than theoretical considerations. Moreover, the approach takes account of only one process, namely risk

heterogeneity, which contemporary theory suggests affects the spatiotemporal distribution of crime.

Prospective Mapping

Prospective mapping is an attempt to develop the way that people think about crime forecasting. In the first iteration of the approach, a simple model was developed to emulate the regularities observed in offender foraging activity as well as time-stable (spatial) variation in risk. To help explain the model in an easily visualized way, an analogy with disease contagion can be used. Consider that the research discussed shows that when a crime is committed at one location, the offender responsible is more likely to commit others nearby swiftly. In this way, an offender's crime series may be thought of as a footprint of foraging activity. Moreover, each crime may be thought of as signaling the location of where others are likely to next occur. Much like the way a disease is communicated in space *and* time, so too it appears is the risk of crime.

To express this process in mathematical terms, a diffusion process is modeled. To elaborate, every crime is assumed to elevate the risk of crime at that location and to those nearby. The strength of this effect is assumed to decay as a function of space. The intensity of risk is also modeled as a function of time; crimes that occurred recently are assumed to confer the greatest risk. In computational terms, this is a refinement of the method used to produce KDE maps. However, it has its origins in theory and explicitly considers how regularities in offender decision making might influence crime patterns. This conceptualization lends itself to future development, whereas simply assuming that the future will reflect the past does not.

For example, it is possible that the risk of crime may not “spread” equally in all directions. It may instead be anisotropic, spreading (or being impeded) in some directions with a greater probability than others. Features of the physical landscape may systematically influence where the foraging offender burgles next. For example, offenders may develop the best awareness for locales that are highly accessible and interconnected with others. This may affect targeting decisions that make the probability of crime highest in those locations near to and most easily connected to previously burgled locations.

Other features of the environmental backcloth may influence targeting decisions in similar ways.

Forecast Accuracy

The accuracy of the basic prospective mapping approach has been compared with that for KDE and thematic mapping for both urban and rural areas. Results published so far suggest that prospective mapping is the most accurate; it can predict the future locations of a greater number of crimes per unit area. For one study, it was shown that thematic maps, which were generated using a police beat geography, did not exceed chance expectation.

Recent work has also examined the forecast accuracy of an enhanced version of prospective mapping for which a simple *opportunity surface* was included. For this version, the distribution and density of potential targets (homes) was modeled, along with a crude measure of area connectivity. Thus, an account was taken of the fact that there would be more targets at some locations and that some areas would be easier to travel to and from than others. Doing so improved the accuracy of the model even more.

This leads us to a second method of assessing the utility of crime maps: the ease with which areas can be patrolled. A map that predicts more crime than another may be little use in a police operational context if the identified areas are scattered. Relative to a few coalesced hot spots, patrolling a series of dispersed locations would result in officers spending a greater amount of time traveling between high-risk locations than policing them. Thus, a second way of comparing the utility of different methods of crime forecasting is to consider how compact (or easy to patrol) they are. In this respect, prospective maps seem to be as compact as KDE maps, perhaps more so.

Practical Application

To be used efficiently in a police context, forecasting methods need to be developed in ways sensitive to the demands of operational policing. In a recent field test of prospective mapping, forecasts were generated for each police shift, ensuring their continued relevance over the course of the day. This approach was welcomed by those who used it to the extent that they asked for its extension to other crime types.

To date, prospective mapping has only been tested for burglary. Although such a crime-specific tool is useful, its application may be limited in all but the most burglary-infested areas, as operational police officers have to deal with a range of crime problems not just burglary. Ideally, forecasting tools used to inform the deployment of police patrols should predict where the highest concentration of all crime is likely. Such forecasts, of course, could be weighted in terms of crime seriousness or in terms of the operational priorities of the day, so that different types of crime are afforded appropriate importance.

To achieve this, the research agenda includes acquiring a more complete understanding of patterns of crime for different types of events. Existing research suggests that several event types—including theft from a motor vehicle, bicycle theft, shootings, and insurgency in Iraq—cluster in space and time, but other patterns might be discerned using statistical techniques unconsidered hitherto. Other challenges include determining how to optimize forecasts produced for combinations of different types of crime and how these might inform patrolling routes to and from, as well as within areas predicted to be crime hot spots.

PROTECTION/RESTRAINING ORDERS

Domestic violence can be characterized by a variety of physical, social, sexual, economic, and psychological attacks against many groups, including current and former significant others, family members, and children. Even though domestic violence can cross socioeconomic, ethnic, and gender lines, most common and popular knowledge of domestic violence relates to female abuse perpetrated by men. The Centers for Disease Control and Prevention estimate prevalence rates for domestic violence at about 4.8 million people per year in the United States. An often sought-out solution to the abuse comes in the form of a protective or restraining order. These orders, which are issued by a civil court order, restrict the contact of the defendant to the plaintiff. In theory, because the order is a civil rather than a criminal proceeding, a victim might be more willing to take action in hopes of minimizing potential retaliation.

Process of Obtaining an Order

A protective order may be referred to as a restraining order, emergency protective order, or peace bond. Although the limitations placed on a protective order can vary, they typically include an order for the defendant to (1) stop violent acts, (2) stay a certain minimum distance from the plaintiff, (3) attend a treatment program for the defendant, and/or (4) evict the defendant from a residence. Although the process and actual type of protective order may vary from state to state, a few unifying

factors are the same. Usually, a temporary or emergency protective order can be obtained first; in most states, these are referred to as an ex parte order, which is also called a 10-day order. An ex parte decision is one decided by a judge when one party (and not the adversary) appears. This protective order is usually valid for 2 weeks, at the end of which a new hearing with the defendant present is held whereby the plaintiff can extend the protective order for a longer period of time (e.g., typically 1 year). This duration again varies from state to state based on specifics of the order and state legislation. Even though these legal services exist to at least partially protect a victim of domestic violence, the statistics of actual usage are low. For example, research estimates that only 16.4% of rape victims, 17.1% of physical assault victims, and 36.6% of stalking victims obtained a protective order after their most recent encounter with a domestic violence situation.

Disadvantages of Protective Order

Even though a protective order can provide civil litigation to stop violent action legally, as well as criminal charges if the order is violated, the protective order still has several unique disadvantages. For example, in some states, a protective order is only available to those who can provide the court with proof of cohabitation or marriage. Other possible problems include the lengthy process of obtaining a protective order and the subsequent hours spent away from work, children, or family that is required for negotiating through the court process. Furthermore, there may be a "dead link" between the actual protective order and the law enforcement agents who must enforce it. That is, the nonenforcement of a valid protective order directly affects the plaintiff's views on the efficacy of his or her protective order, and it may prevent future attempts to secure a protective order.

Protective Order Risk Factors

Beyond the efficacy of the protection orders is the notion of who is most at risk for future re-abuse. Risk factors for re-abuse include sharing biological children with the abuser, whether the defendant was arrested, and prior abuse history. The presence of biological children contributes to higher rates of

re-abuse because of conflict and violence that occur as a result of custody and visitation issues. The evidence for whether arrest acts as a deterrent is mixed. Some research has found that the probability of postprotective order abuse is *reduced* if the abuser is arrested at the time of the incident that led the victim to obtain a protective order. However, other research does not find any effect of arrests on the likelihood of re-abuse. Prior domestic violence is also a risk factor for re-abuse.

Some research has suggested that socioeconomic status (SES) may be influential in the likelihood of re-abuse after a protective order is issued. Women who are more economically dependent are potentially less likely to leave the abusive relationship. That is, women may remain with their abuser out of economic necessity and may return to abusive relationships for financial reasons. Moreover, individuals who have a “stake in conformity” have more to lose by a re-arrest and, thus, may be less likely to re-offend.

Race is also a potential risk factor; however, it is unknown to what extent race is confounded with SES. Research has shown that Black women are more at risk than White or Hispanic women. Furthermore, research finds that Black women have the highest prevalence of being beaten (67%) in comparison with White and Mexican American women. Black women also report spending more days at a women’s shelter when compared with their Hispanic and White counterparts. Interestingly, Black women also experience less of a decline in re-abuse than do their White or Hispanic counterparts after the issuance of a protective order.

Research on victim-offender relationships indicate that police may respond differently depending on the length of the relationship. Being in a long-term relationship (5 or more years) is associated with lower rates of reported re-abuse, but only for women in higher SES groups. This may be a reporting effect, as early abuse in a relationship is more likely to be reported and women in long-term relationships are less likely to contact police for assistance.

PSYCHOLOGICAL AND BEHAVIORAL CONSEQUENCES OF VICTIMIZATION

Research examining the psychological and behavioral consequences of victimization was missing from victimization literature up until about 20 years ago. Although many scholars have assumed that there are indeed mental health costs associated with victimization, a large portion of national surveys have failed to ask specific psychological health questions regarding the time period after the victimization. More specifically, it is important to know the types of mental and behavioral health problems that affect victims, so that resources can be better allocated and education and assistance programming can be put in place. This entry offers a definition of the psychological and behavioral consequences of victimization, discusses the types of mental health problems that can occur as a result of being a victim, provides prevalence rates of such mental health consequences, and ends with a discussion on prevention.

Definitions

Mental health is commonly defined as the absence of mental disorder; however, according to the World Health Organization, it is more than that. It is also “a state of well-being in which every individual realizes his or her own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to her or his community.” *Merriam-Webster’s Medical Dictionary* defines mental health as “the condition of being sound mentally and emotionally that is characterized by the absence of mental disorder (as neurosis or psychosis) and by adequate adjustment especially as reflected in feeling comfortable about oneself, positive feelings about others, and ability to meet the demands of life.” Those who suffer psychological and behavioral problems after victimization may therefore have problems with adjustment to daily life, work, and community; have negative feelings about themselves or others; and/or lack mental and emotional stability. Victims also may experience fear, ranging from mild to debilitating levels.

Types of Psychological and Behavioral Health Consequences

The first type of psychological consequences occurs immediately after the victimization and are typically of a short duration. Such behaviors that fall under this category would be fear, shock, anxiety, confusion, helplessness, guilt, shame, depression, social withdrawal, and low-self esteem. More serious in nature are the second type of psychological consequences, which are more chronic in nature, such as posttraumatic stress disorder (PTSD), severe depression, and borderline personality disorder (BPD). PTSD rates for sexual victimization have ranged anywhere from 30% to 65% in the research, depending on how and when the symptoms were assessed. Research on depression has also produced mixed findings, with some researchers finding a connection between victimization and depression, and others finding no link at all.

A multitude of other psychological disorders and problem behaviors are associated with victimization. Such problems may include (but are not limited to) sleep disorders, eating disorders, self-mutilation, preoccupation with physical appearance, somatoform disorders, sexual dysfunction,

alcohol/drug abuse, and suicidal behaviors. The extent to which a victim experiences mental health and/or behavioral problems can depend on many factors, including the type of victimization, victim-offender relationship, the environment in which the victimization occurred, current or past life circumstances (e.g., divorce, financial stress, or death of a loved one), and a family history of mental health problems. Also, psychological disorders and behavioral problems often co-occur or occur along with physical health problems.

Prevalence

The National Violence Against Women Survey (NVAWS) provides some national-level estimates on the extent to which psychological and behavioral problems occur after victimization. In the case of rape victims, 33% of females and 24.2% of male victims sought counseling from a mental health professional as a direct result of their victimization. Similarly, 30% of female and 20% of male stalking victims reported having gone to counseling after being victimized. In regards to PTSD, approximately 25% of those criminally victimized develop some either short- or long-term features. Most of the literature has found that while men and woman both suffer psychological health problems as a result of victimization, women experience psychological problems at a higher rate than men. Unfortunately, there is little available as to the true extent to which psychological and behavioral problems arise after victimization. This scant amount of research indicates that much more needs to be done in this area.

Prevention

Regardless of the extent to which mental health and behavioral problems occur after victimization, much needs to be done in the form of prevention. The diversity in possible mental health outcomes can be attributed to many factors, which means that prevention needs to occur at all levels. First, prevention efforts need to be in place for decreasing the overall number of personal crimes. Second, educational programs need to be implemented so that individuals can better prepare and protect themselves against possible future victimization. Also, educating the

population about victimization in general is always important, especially when it comes to educating those groups that may be at a greater risk for victimization (e.g., college students and females). Finally, prevention efforts need to focus on providing help and assistance to victims immediately after the victimization has occurred, which is the period when victims are most vulnerable.

PSYCHOLOGICAL/ EMOTIONAL ABUSE

Intimate partner abuse is a common problem that has received considerable attention since the 1980s. When discussing intimate partner violence, individuals often focus on physical abuse, probably because it is more visible than psychological abuse and receives more attention from the justice system. However, at the beginning of the battered women's movement and in recent years again, researchers and practitioners have emphasized the importance of understanding the role of psychological abuse in the abusive relationship as well. As a risk factor for future violence, psychological abuse has importance in considering intervention and prevention of intimate partner violence. Beyond its relationship to physical violence, however, women frequently report that psychological abuse causes them greater distress than physical acts of violence, which makes it an important part of an abusive relationship to understand on its own. This entry provides a definition of psychological abuse, describes types of psychological abuse, details correlates and consequences of psychological abuse, and ends with concluding remarks related to challenges for the future. The focus here is on the relationship dynamic that is best documented in the research literature—where a male partner is abusive toward a female victim.

Definition

Although awareness of psychological abuse has increased, there is no generally accepted definition of psychological abuse in the research literature. Diane Follingstad has proposed that the current absence of a unified definition is because of the lack of clarity about what constitutes a psychologically abusive behavior. For instance, the complex dynamics in relationships may explain certain actions that on the surface could be viewed as psychological maltreatment, but on extended examination may

be deemed justifiable given specific contexts of the relationship. Taking context into account is hampered by the widespread use of self-report measures, which make it difficult to form a complete picture. Refining our understanding of psychological abuse, according to this line of thinking, will require better measurement and more emphasis on a holistic view of the relationship.

One proposed pattern of abuse in intimate relationships that is useful in tying together various definitions is called coercive control. Coercive control is a pattern of behavior in which one partner aims to control the other through a wide range of tactics, only some of which involve physical force. The context of whatever physical violence occurs is behavior that is psychologically abusive and meant to achieve and maintain dominance in the relationship. A useful schematic that captures this idea is Ellen Pence's Power and Control Wheel. The wheel has as its spokes categories of abusive behaviors, all of which are theoretically aimed at the same goal of gaining and maintaining power. This tool is often used by practitioners to assist victims in identifying and normalizing their experiences that fall outside the concrete definition of physical abuse.

Psychological abuse in the theoretical framework of coercive control leads to continuous violations of the victim's freedom, rights, and resources. Two main categories of behaviors that batterers use when applying coercive control are isolation/dominance (social isolation, intimidation and deprivation of resources such as food, clothing, money, and transportation) and verbal/emotional abuse (the willful infliction of emotional pain by the use of verbal and nonverbal threats and humiliation). It is possible for psychological abuse to exist outside the context of coercive control, and in such cases, the abusive behaviors are likely to fall into this latter category.

Despite its centrality to women's experience of abuse, most forms of psychological abuse are legal. An exception is stalking. Patricia Tjaden and Nancy Thoennes, who authored the largest recent study of violence against women, defined stalking as a "course of conduct directed at a specific person that involves repeated (two or more occasions) visual or physical proximity, nonconsensual communication, or verbal, written, or implied threats, or a combination thereof, that would cause a reasonable person fear" (p. 5). Although variability in this legislation is found across states, some degree of victim fear is

generally part of the legal definition of stalking; there has been controversy regarding the reasonableness of this threshold.

Risk Factors and Correlates

A large literature is available about characteristics that put women at risk for intimate partner violence in general. Less information can be found about what environmental or personal characteristics predict psychological abuse specifically, but the existing research has indicated several possibilities. In terms of demographic variables, there is evidence of increased risk for psychological abuse in couples of higher education levels and among women who are employed outside the home. Batterers who have criminal records are also more likely to be psychologically abusive in intimate relationships.

Batterers' personality characteristics have also been the target of research in this area. For instance, batterers who exhibit higher levels of anger, as well as passive/aggressive and self-defeating personalities, seem to be more likely to be psychologically abusive toward an intimate partner. Similarly, some preliminary evidence suggests that feelings of rejection stemming from childhood may be related to psychological aggression toward an intimate partner.

Also, specific dynamics in the intimate relationship make it more likely that a woman will be psychologically abused. It was found that men who report lower marital adjustment (connecting with one's partner and engaging in activities together) and an increase of demands by wives tend to withdraw more from their spouse and to more likely be psychologically abusive. In addition, psychological abusers tended to have a more fearful attachment style toward their partners, which is characterized by relationship anxiety and fear of rejection or being hurt, as well as anxiety if they are too close or too distant from their partner.

Finally, prior violence is a red flag for psychological abuse. Research has shown that in general the more frequent and severe past abuse has been, the more likely it is for the psychological abuse to continue to occur in the future.

Consequences

Many studies support the relationship between psychological abuse and mental health problems.

One of the strongest connections is to posttraumatic stress disorder (PTSD). Researchers have shown that psychological abuse is uniquely related to PTSD, above and beyond physical abuse. Studies have yielded similar findings for the relationship between psychological abuse and depression, self-esteem, increased level of fear, and anxiety.

Clear evidence indicates that being in a psychologically abusive relationship is damaging to a woman's physical health because of its relationship with stress. Some practitioners have proposed that psychological abuse leads victims to experience levels of stress that in many instances is higher than stress related to physical assault. This increase in stress could result in victims experiencing multiple stress-induced ailments, such as arthritis, chronic pain, migraines and frequent headaches, stomach ulcers and spastic colon.

In addition to mental health problems related to psychological abuse, stalking could be particularly harmful in increasing the victim's fear and preventing her from going through her daily routines (such as going to work or school). Research findings support the unique contribution of stalking to psychological distress. For example, researchers found that women who were stalked reported more PTSD and depressive symptoms, as well as higher levels of substance abuse, compared with those who did not report any stalking. In addition, the longer the stalking goes on, the more worried victims become about their personal safety.

Finally, when psychological abuse includes the social isolation of the victim, it decreases the social support that might otherwise help her cope. The batterer initiates this pattern by preventing the victim from speaking to her friends and family, as well as interfering with her education and independent employment. Over time as the victim is unable to maintain social contacts, she becomes increasingly alone. Studies have shown that social isolation places people at higher risk for depression and anxiety. Thus, the social isolation exacerbates the negative mental health consequences of abuse.

Challenges for the Future

Psychological abuse can take many different forms, including isolation and dominance, verbal and emotional abuse, and stalking. It is often a precursor to physical violence and has been shown to be

more detrimental than physical violence in relation to mental health outcomes. In addition, psychological abuse is related to various physiological problems, such as stomach ulcers, migraines, frequent headaches, and chronic pain, and it contributes to social isolation, which then exacerbates mental health problems.

Although many advances have been made in the field in our understanding of psychological abuse, many unanswered questions and challenges still exist. First, the only form of psychological abuse that is currently against the law is stalking, and there have been some suggestions that legislation should be broadened to address the broader range of psychologically abusive behaviors under the umbrella of coercive control. The extent to which the dynamics described here generalize to relationships where the female partner is aggressive, or where partners are of the same sex, also requires exploration. Predictors of psychological abuse also need to be investigated even more. Finally, research with Hispanic, Eastern European, and Indian groups has suggested that at least within some cultures, psychological abuse is less likely to be recognized as a form of intimate partner violence. Such findings suggest a need for intervention with victims of this kind of abuse as well as prevention more broadly.

PSYCHOLOGICAL/EMOTIONAL ABUSE, MEASUREMENT OF

Psychological/emotional abuse refers to nonphysical aggression or maltreatment that causes psychological distress and is perpetrated against an intimate partner. Although psychological/emotional abuse may occur in a variety of close relationships (e.g., parent-to-child), this entry is limited to measurement of abuse that is perpetrated against an intimate partner.

Psychological/emotional abuse takes different forms, including domination, control, isolation/restriction, humiliation, criticism, ridicule, or threats of violence. The measurement of psychological/emotional abuse is generally accomplished using self-report instruments that assess how frequently an individual’s intimate partner has engaged in certain behaviors. A higher score on such a measure indicates a higher incidence of such abusive behaviors. The measurement of psychological/emotional abuse is of primary use to researchers who are interested in studying possible causes of such abuse, its relationship to other types of abuse, correlates of psychological/emotional

abuse, and outcomes for individuals who have been psychologically victimized by their partners. Most often, this research has focused on male-to-female intimate partner violence (IPV) because male-to-female IPV has been shown to be both more common and more deleterious.

Although research focusing on psychological/emotional abuse in intimate relationships is a more recent development, preceded by decades of research focused primarily on physical abuse, several measures have been developed by researchers that have demonstrated utility, reliability, and validity to assess the incidence of psychological/emotional abuse. These measures assess a range of behaviors that include verbal abuse and aggression, domination, intimidation, denigration, and isolation/restriction.

Sample Measures

The measurement of psychological/emotional abuse was initially done using general measures of IPV that included items to assess nonphysical abuse. For example the Conflict Tactics Scale (CTS), first introduced by Murray Straus in 1979, assesses a range of behaviors that may occur between intimate partners, several of which are categorized as “verbal aggression.” The respondent is given a list of 19 relationship behaviors and is asked how many times each occurred within the past year on a scale ranging from 1 “once in the past year” to 6 “more than 20 times in the past year.” Psychological/emotional abuse tactics listed on the CTS include “insulted or swore at him/her” and “threatened to hit or throw something at him/her.” The CTS was eventually revised to include more items and a wider range of experiences. However, its general approach is still to measure only the frequency of behaviors between partners.

The Index of Spouse Abuse (ISA) was developed shortly after the CTS and was designed to be used in clinical settings as a self-report instrument to assess the frequency of both physical and nonphysical abusive experiences. Like the CTS, the ISA measures the frequency of relevant experiences, with choices ranging from 1 “never” to 5 “very frequently.” Both the CTS and ISA have been widely adopted as measurement tools for psychological/emotional and physical IPV.

As psychological/emotional abuse received more attention, researchers began to develop instruments

specifically for its measurement. These followed the same format used for the CTS and ISA: Respondents were given lists of experiences and asked to rate how frequently they occurred in their intimate relationships. One of the most commonly used assessment tools of this sort is the Psychological Maltreatment of Women Inventory (PMWI). In this tool first developed by Richard Tolman in 1989, respondents rate the frequency of experiences using a 5-point scale ranging from 1 "never" to 5 "very frequently." The two subscales are dominance/isolation and emotional/verbal. Sample dominance/isolation items include "my partner monitored my time and made me account for my whereabouts" and "my partner restricted my use of the telephone." Sample emotional/verbal items include "my partner called me names" and "my partner yelled and screamed at me." The full PMWI consists of 58 items; a short-form derivative has 14 items.

Also available is the Multidimensional Emotional Abuse Scale (MDEAS), which was developed by Christopher Murphy and Sharon Hoover and published in 2001. The MDEAS is a 28-item self-report questionnaire that assesses how often the respondent and his or her partner engaged in psychologically abusive behaviors during the preceding 4 months. Like other measures of psychological/emotional abuse, respondents are instructed to review a list of behaviors and note how frequently they occurred on an ordinal, numerical scale. Several other instruments are currently available to measure psychological/emotional abuse, which include the Index of Psychological Abuse and the Subtle and Overt Psychological Abuse Scale, among others. It may be noted that all the commonly used tools for measuring psychological/emotional abuse assess only the frequency of abusive behaviors and provide little if any information as to the severity, duration, or context. Additional information, including information about outcomes and correlates of the abuse, must generally be gathered using other instruments.

Measurement Issues and Future Directions

The measurement of psychological/emotional abuse is complicated by various factors. First, psychological/emotional abuse is not fully defined; some disagreement remains among researchers

and clinicians as to what constitutes such abuse. Second, unlike physically abusive behaviors, which are considered largely unacceptable in intimate relationships, psychologically abusive behaviors are more subjective and are often more subtle in their presentation and effect. This makes the threshold for "abuse" for psychological/emotional abuse less clearly delineated than the threshold for physical abuse. For research purposes, it would be helpful to assess not only the frequency of psychologically aggressive behaviors but also the severity, duration, and context, as well as the subjective effect on and the experience of the victim.

In addition, the measurement of psychological/emotional abuse is complicated by the fact that the terminology for psychological/emotional abuse is not standardized. Furthermore, whereas several measures have been designed to assess psychological/emotional abuse, some of which have been described briefly here and have been shown to have strong psychometric properties, no single measure has established itself as the gold standard specifically for the measurement of psychological/emotional abuse. Thus, although measurement of psychological/emotional abuse can be accomplished, psychological/emotional abuse remains a construct that is not clearly defined, and whose measurement deserves more development.

PUBLIC OPINION AND CRIME PREVENTION, INTERNATIONAL

The level of public support for crime-prevention policies and practice is well understood by governments and policing agencies. Public confidence in emergency services, including the police, is widely acknowledged as a critical element in the maintenance of public safety and social order.

Understanding Public Opinion Research

Various methodological issues come into play when considering public opinion research on crime and criminal justice issues. How it is that people become aware of crime-prevention issues can be viewed as stemming from four main sources. First, self-reported attitudes on crime are largely media driven and focused primarily on sensational and often violent offenses. Crime-prevention efforts are typically less interesting to the news media as they focus on seemingly mundane elements such as environmental design, city planning, and preventive policing. In essence, the noteworthy crime-prevention projects are muted by their own effectiveness. Second, news coverage of successful prevention schemes are typically broadcast by the agencies from which they were derived or perhaps the local stakeholders, such as community interest groups and the like, and as can be expected, these schemes are greeted with a certain amount of skepticism or even cynicism. The third major information source

regarding crime-prevention issues is, of course, from direct (firsthand) personal experiences of successes and perhaps more vividly, failures. Fourth, people generate understandings of the experiences of others through friends and family, and friends-of-friends. Of course, it is not necessary for members of the public to have accurate knowledge about a given crime-prevention program for them to report an opinion on the matter; that is to say, their understanding of the issues is sufficient, and researchers are keen to capture what people think is the case, regardless of its connection to a more empirically valid reality.

International Trends

A recent review of public opinion research on crime-prevention policies and practice in Canada has had limited publication in peer-reviewed journals, as polling work on crime-related issues seems to find its way into unpublished works, such as government reports and special within-agency documents. The Canadian government's projects are coordinated via the National Crime Prevention Centre (NCPC). Canadian attitudes since the 1990s have continued to support prevention as the best mechanism to fight crime, as opposed to reactionary strategies to deal with crime that has already occurred. A recent, nationally representative, opinion poll commissioned by the NCPC in 2004 found that Canadians rated prevention as the principle goal of the criminal justice system at a rate of 2:1 over punishment. Furthermore, nearly three quarters of Canadians considered prevention programs to be more cost-effective than law enforcement efforts.

Parenting

Canadians routinely identify crime prevention as something that is outside of the criminal justice system, noting that parenting and other social elements (supervised activities for after-school hours, training kids to learn responsibility, and so on) are more primary. As with the Canadian studies, approximately 60% to 70% of those polled in England and Wales reported "parenting" as the first avenue of crime prevention; this finding is observed in more than a dozen other European nations.

Public Awareness of Crime Prevention Programs

Canada and the United Kingdom share noticeably lower rates of citizen awareness of specific crime-prevention programs (schemes) than reported in the United States. The Canadian Urban Victimization Survey noted that about one-half of Canadians could name a specific crime-prevention program (Block Parents Program was the most noted), but less than 10% of those polled participated in such a program. Polling in the 1980s and 1990s showed higher rates of awareness (at approximately two-thirds, rather than one-half), and participation rates in the 1990s of 12% to 28%, with Neighborhood Watch being the most frequent program for participation. More recent work in Canada based on nationally representative samples for 2000 and 2003 shows a stark downward trend for both awareness and participation. Approximately 40% reported “general awareness” of prevention programs, but only 21% could name one for 2000, and this proportion dropped to 15%. For both years, Neighborhood Watch was most often mentioned, with the next most frequently identified program (Block Parents) at 5% and 15% for 2000, 2003, respectively.

Future Research and Recommended Improvements

Public opinion studies suggest that there is substantial support for governments to pursue programs and schemes to prevent crime that have evidence-based support in the research community. Public support of crime prevention remains consistently high in North America and Europe. More work needs to be done to understand the public’s role and views of crime-prevention schemes in South America, Africa, Eastern Europe, and parts of Asia.

Recommended improvements will differ for each jurisdiction but typically include adding more specific awareness and participation questions to existing annual and regularly occurring national surveys, such as victimization and general social surveys. Surveys need to focus on specific programming and participation practices to assist policy makers and analysts in understanding more of how to generate the most benefit from existing crime-prevention/reduction efforts. Furthermore, research on the

public’s awareness of, and participation in, crime prevention needs to be consolidated and shared more effectively—at least at the national level. Public opinion work on crime prevention, experts suggest, needs to follow a similar path as those working on the same issues but for confidence in the criminal justice system. These last two issues may be improved simultaneously by encouraging academic or governmental institutions to setup databases of related public information polling.

PUBLIC OPINION AND CRIME PREVENTION, UNITED STATES

Public opinion is defined as a set of preferences expressed by a sizable number of people toward an issue, policy, or practice of general importance to that group. The group may be as broad and large as the entire citizenry of the United States, or it may be more constrained such as the residents of a single neighborhood. In either case, the public is considered to be a group made up of the general populace, not criminal justice practitioners, policy makers, or those who represent a particular interest. Public opinion finds its relevance to crime prevention as

a consideration in policy making. Although those who formulate crime-prevention policy do not blindly follow public preferences, a democratic society demands some correspondence between the will of the people and public policies. Because political power is broadly distributed and the public has the ability to influence policy in America, it is important to know what the public thinks.

Public opinion on crime prevention includes views on general approaches to crime as well as expressions of support for or opposition to particular crime-prevention activities. Broadly, at least two thirds of Americans embrace the ideal of preventing crime by addressing social and economic problems. The remainder of Americans instead think that crime should be prevented through efforts to deter potential criminals. Although some disagreement exists and some policies are embraced more widely than others, the American public tends to express favorable opinions toward a large number of specific measures to prevent crime initially or to prevent repeated crime. Support exists for gun control, early intervention, incapacitating repeat criminals through long prison sentences, Neighborhood Watch programs, capital punishment, and offender rehabilitation programs, among others. People tend to oppose crime-prevention measures that greatly erode civil liberties. Public opinion on four issues that have been researched the most thoroughly is described in more detail below.

Gun Control

The public generally supports governmental regulations on personal ownership of firearms. People tend to believe that the availability of guns helps explain why the United States has higher levels of violence than other countries, and greater control over guns may prevent crime.

Many specific policies are listed under the umbrella of gun control, and opinions often vary depending on whether the people expressing their views are gun owners or not. In 2007, approximately half of citizens polled believed that gun laws should be stricter, and an additional two fifths thought they should remain the same. Less than one in ten thought they should be made less strict. In the preceding 20 years, the percentage of Americans who thought laws regarding firearm sales should be stricter reached nearly 80%. Notably, gun owners are less likely to favor strict gun laws. Even gun

owners, however, tend to embrace minor restrictions, such as requiring that a permit be obtained before purchasing a firearm, waiting a short period before taking possession of a purchased handgun, and registering ownership of firearms. In contrast, at least half of the public opposes a complete ban on handguns. Opposition to a ban rises to about four of five among gun owners.

Early Intervention

The public expresses considerable confidence that families, schools, and targeted programs can lead at-risk children out of crime. In all, 80% to 90% of Americans support preschool programs for disadvantaged youths, parental skills training programs, after-school education and recreation, drug use avoidance programs, and truancy-prevention initiatives. For juveniles, the public is particularly hesitant to endorse punitive approaches such as locking up more children. Instead, they favor interventions that will prevent troubled youths from becoming involved in delinquency, gangs, or violence.

Capital Punishment

Public opinion on capital punishment has been researched more thoroughly and for a longer period than perhaps any other crime-prevention issue. Currently, when asked if they support the death penalty for someone convicted of murder, about 70% of Americans say yes. For the past 25 years, support has varied no more than about 5% from this level. At its lowest point—during the mid-1960s—Americans' support for this sanction dropped to less than half.

A level of complexity is added to public opinion toward capital punishment when consideration is given to how opinion questions are asked and which portion of the public responds. When life in prison without the possibility of ever being released is explicitly offered as an alternative sentence for people convicted of murder, the portion of the public who still endorse the death penalty is substantially lower. When opinion is measured more concretely, such as by asking whether a person would be willing to carry out an execution, far fewer people are willing to embrace the death penalty. In terms of subgroups of the American population, researchers have found fairly consistently that women and African

Americans hold less favorable opinions of capital punishment than men and Whites.

Additional evidence speaks to whether the public favors capital punishment as a crime-prevention measure or for other reasons. A third of the American public believes that the death penalty serves to deter others from committing murder. Furthermore, when asked for their reasons for supporting capital punishment, about 10% mention incapacitation. About four in ten Americans say they support it because it is what the offender deserves.

Correctional Goals

Information on public opinion about correctional goals has been gathered in tremendously diverse ways, and a general pattern has emerged. The American public voices strong support for rehabilitation, deterrence, and incapacitation as critical aspects of corrections. Thus, the public favors strategies that seek crime prevention through treatment of offenders, punishment that demonstrates the negative consequences of crime to the offender and to other potential offenders, and restrictions that block an offender's ability to commit additional crimes.

abuse, theft, burglary, robbery, and white collar crime. Society has a perception of victims of these and other crimes that is not always accurate. These perceptions are influenced by several factors including the media, myths about crime, and characteristics of the victim. Examples of perceptions held by society about crime victims are that people are to blame for their victimizations, that people deserve to be victimized because of who they are and that people recover from victimization quickly. These perceptions contribute to negative reactions to crime victims on behalf of the public and the criminal justice system. This entry discusses the perceptions of crime victims in America, contributions to these perceptions, and the impact of these perceptions on those victimized by crime.

Media Influence

There are several contributing factors to the American public's perception of crime victims. In part, perceptions are based on what people observe being reported in the news and what they view on television and in movies. Generally speaking, media portrayals of crime victims are frequently inaccurate and contribute to the manner in which victims are treated in society. Some television shows portray victims as liars who report crimes to cover up their own wrongdoing. Additionally, the news media report only a small portion of the crime that happens in American society. The crimes that are reported to the public tend to be those that are considered more serious in nature such as stranger rape, homicide, crimes that are committed with firearms, and crimes against the very old and the very young. What the news fails to report is that most victims of violent crimes are teenagers or young adults, that most people are victimized by those known to them, and that many people are victims of crimes that are never reported to criminal justice officials. In a more positive impact on the public perception of crime victims, media coverage has brought more attention to certain types of crimes. Child sexual and physical abuse cases are frequently covered by the media and have increased public awareness about these victimizations. The media has also contributed to public knowledge about intimate partner violence. Specifically, news coverage about women who are murdered by a current or former intimate partner

PUBLIC PERCEPTIONS OF VICTIMS

People can experience many types of victimizations, including rape, domestic violence, child

has contributed to an increase in awareness about intimate partner violence. However, the cases that are covered are generally extreme, which leaves most cases without media publicity.

Perceptions of the American Public

Americans hold many perceptions of crime victims; many of them are inaccurate and few of them are positive. Victims of sexual assault, intimate partner violence, and drug-related crime tend to be perceived more negatively by the American public than are victims of other crimes. Rape victims are frequently perceived as women who are sexually promiscuous, who dress provocatively, who are careless, and who have poor judgment. In reality, sexual assault victims are frequently victims of opportunity. This means that the person who commits the crime capitalizes on whatever circumstances provide him or her with the least resistance and least chance of reporting from the victim. It is also commonly assumed that sexual assault victims are always women or girls; however, men and boys can be victimized by sexual assault.

One public perception of crime victims is that they should act a certain way after the victimization. The stereotypical view is that victims should be hysterical and extremely upset. In fact, there is no "correct" way to react to victimization and reactions vary from person to person. The perception of how a person should respond to crime is detrimental to the victim because if a person does not respond as expected, he or she is frequently accused of making a false report.

A related issue is a perception that crime victims are mentally unstable. This perception stems in part from how people respond to their victimization. When victims do respond hysterically, others may have the impression that the victim is mentally ill. The dual expectations of the public—respond calmly and there is disbelief; respond hysterically and there is mental illness—puts victims in a precarious circumstance. Unfortunately, many people are unstable because of mental illness or other issues, and these victims are at a higher risk for victimization because of their difficulties. However, because of the negative perception of mentally unstable persons, they are less likely to be believed than others who report victimization.

Sometimes, crime victims are perceived by the public to be deserving of what has happened to them. This is frequently the case for victims of intimate partner violence, sexual assault, and people who are victimized in high-crime areas. It is assumed that people who experience these victimizations have done something to deserve it. A popular perception about intimate partner violence is that if a person stays in a violent relationship, then he or she deserves to be treated poorly. In reality, most people in battering relationships cannot leave because of a variety of reasons, including financial difficulties and fear of retaliation. Sexual assault victims are assumed to have "led the other person on" and therefore deserve what happened to them. Inner-city crime is believed by the public to be largely drug related, and victims in the inner city are frequently thought to be drug users or abusers who are deserving of whatever befalls them. However, many people who are victims of drug-related crime are innocent bystanders who are caught in the middle of a dispute. In addition, most of the inner-city population is law abiding and resides there by choice or because of circumstances (e.g., being unable to afford to live in another part of the city).

Another perception is that people who report being victimized by crime lie for personal gain, to protect their reputations, or to be malicious toward another person. This perception is most frequently applied to rape victims and victims of domestic violence. However, sometimes the news media perpetuates this inaccurate perception by focusing its reports on those cases that are proven to be false. Popular television shows also have storylines that focus around false crime reports. Even though false reports of victimization do happen, most reported victimizations are valid. In the eyes of the public, however, victims of certain crimes are viewed with skepticism until it can be proven that they are telling the truth.

Sometimes, the perception of crime victims is influenced by personal characteristics of the victims, including sex and race. For example, male and female victims of crime are perceived differently by the public. This is particularly true when men are victims of crimes that traditionally target women. When men are sexually assaulted, society tends to perceive them as homosexual or weak. Male victims are not looked on with as much sympathy as

female victims, and this impacts the willingness of men to report their victimizations. Similarly, when men are victims of intimate partner violence, they are perceived as unmanly and unable to “control” their women. The same negative perception is not extended to male children, however, who are regarded sympathetically because they are not yet strong enough to avoid victimization. In contrast, whereas female victims are generally perceived as less deserving of their victimizations, particularly when the victimization is at the hands of males, on many occasions they are still blamed for what happened. This especially occurs when women step outside of society’s norms and roles for them. For example, society tends to hold women to a higher standard with regard to sexual activity, and when a sexually active woman is raped, society perceives this to be her fault because of her prior behavior.

Race has an impact on the public perception of crime victims. Whites tend to be perceived as less deserving of their victimizations than are people of other colors, races, and ethnicities. The American public views with much sympathy those crime victims in which Whites are victimized by people of other races and ethnicities. In comparison, the American public tends to view crime victims of minority races and ethnicities with less sympathy and sometimes believe they deserve their victimization. However, this sentiment is not extended to child and elderly victims of crime, who tend to be viewed with sympathy regardless of race or ethnicity.

Sexual orientation also has an impact on how victimization may be viewed by the American public. Homosexual victims of hate crimes are sometimes perceived as deserving of what happens to them because people disagree with their sexual orientation.

The biggest misperception about crime victims held by individual members of the American public is that they will never be one. People believe that crime in American society has increased but do not necessarily believe that they will experience a victimization. American people take many precautions against being a victim such as locking car doors, sleeping with the windows closed, and carrying protection such as mace or a firearm. In addition, people tend to believe that victimization occurs at the hands of strangers and only in areas of poverty. In reality, most victimization occurs

between people who know each other, and many property crimes occur in suburban areas. The belief that victimization “will not happen to me” contributes to blaming people for their victimizations. The public assumes that they would have acted more intelligently, therefore avoiding whatever circumstance contributed to the victimization and leading to negative judgments about people who are victimized.

Impact of Perceptions on Crime Victims

Crime victims are impacted by the perception of the American public in several ways. Victims of crime are aware of how they may be perceived and fear being judged negatively. This contributes to a reluctance to report their victimizations to the police or to other authorities. In addition, reporting victimization to the police may require that they testify in court, opening them up to public scrutiny if a jury trial occurs. People are also reluctant to seek assistance in healing psychologically from their victimizations because of the stigma that is attached to the act of seeking out mental health services. Sometimes the perceptions of crime victims can result in positive outcomes. If victims, and the offenders, fit the perceptions that the public holds, victims may be treated with more sympathy. There is a need to educate the general public about victimization to help them form more positive perceptions of crime victims, so that the victims can report their experiences without fear of judgment or poor treatment.

PUNITIVE AND COMPENSATORY DAMAGES

Generally speaking, the law in America consists of two broad categories: civil law and criminal law. These two categories of law differ significantly. Although the civil law has many different subcategories, for the purposes of this entry, the phrase *civil law* will be used to refer to those civil law suits brought by victims to seek redress for acts committed by negligent or intentional acts by a responsible party resulting in damages to the victim. These redresses can include punitive damages, which are meant to punish the offender and to deter future offenses, and compensatory damages, which reimburse the victim for actual damages incurred.

Criminal and Civil Law

The purpose of the criminal law is to protect society from certain acts by the offender that are deemed so harmful that their commission merits official punishment, usually in the form of fines or imprisonment and, for serious violent crimes, even death. It is the state that brings criminal charges against a suspect and not the victim who makes such a decision. Although an individual victim can ask the police or the prosecutor to bring criminal charges, it is the prosecutor who has the sole discretion whether to bring or continue criminal charges. Sometimes, a victim of a crime is eligible for restitution, which is a form of compensatory damages, although it is labeled differently so as to prevent confusion with civil cases.

In contrast, the purpose of the civil law is to resolve disputes between individuals or private entities such as corporations. If a person has been found to violate the civil law through negligence or an intentional act, such as in a personal injury lawsuit resulting from a car accident, then that person, if responsible for the car accident, is usually required to pay damages to the victim. These damages can include compensatory damages but may also include punitive damages.

Damages

The basic form of damages is compensatory damages. Compensatory damages are meant to reimburse

the victim for actual damages suffered. Compensatory damages include payments for medical expenses, property damage, lost wages, and pain and suffering.

Punitive damages are different and are awarded to the victim to punish the offender. Also, the award of punitive damages is meant to deter the responsible party and other persons from repeating the same conduct. Usually, punitive damages cannot be awarded unless the responsible party has been found liable for the harm caused, whether by negligent or intentional conduct, and compensatory damages have been awarded.

There are exceptions to the prerequisite of an award of compensatory damages before punitive damages have been awarded. The major exception is an award of nominal damages. Nominal damages can be awarded when a responsible party has been found to violate certain laws but there were minimal or no actual damages to the victim. In such an event, an award of nominal damages, which usually consist of \$1, will be made. Sometimes, where there is an award of nominal damages, an award of punitive damages can be made. The justification for such an award is to recognize that a wrong had been committed and vindicate certain legal rights. This is usually done in suits for violation of civil rights. For example, when the police violate a victim's constitutional rights, but the victim has not suffered any medical, property, or economic damages and nominal damages have been awarded, punitive damages might be awarded to punish the police and deter the police from repeating the misconduct.

Punitive damages are not awarded in criminal cases; however, they can be awarded in civil cases. The rationale for not awarding punitive damages in criminal cases is that society is considered the victim, and not the individual person, and the punishment is expressed in terms of a fine payable to the state or imprisonment. In contrast, in a civil case, the victim is the person who brought suit and is usually the person who receives the payment of punitive damages.

Punitive damages in a civil case are usually not awarded and not even available to a victim where the responsible party has been merely negligent. Punitive damages are usually available or awarded where the conduct of the responsible party has been grossly negligent, intentional, egregious,

unconscionable, or outrageous. In such a situation, the jury is allowed to select an amount of money to be awarded as punitive damages.

The theory behind punitive damages is that it must be sufficient to punish and deter the responsible party and to place other parties on notice that such conduct will not be tolerated in the future. The general limitation is that the punitive damages should not be excessive. In the past few decades, tort reform has resulted in statutory limits on punitive damages in both the type of civil cases where punitive damages are available as well as the amount of punitive damages available.

As previously discussed, punitive damages are not available in criminal cases. However, victims of certain violent and property crimes are allowed to receive restitution from the offender. The restitution will usually be awarded to the victim as a part of the punishment of the offender at the sentencing phase of the offender's trial. Failure to pay the restitution may result in additional charges being brought against the offender. In the past few decades, the victims' rights movement has resulted in several statutory changes. Relative to violent crimes, many jurisdictions, in addition to allowing

restitution, now allow victims to present an impact statement at sentencing of the offenders.

However, victims of crimes are not limited to relying on just the criminal law and concurrent restitution to obtaining relief. Victims of crimes may also bring civil cases to obtain relief. For example, if a victim of an assault incurred medical expenses and lost wages, directly attributable to the assault, then the victim could bring suit against the offender to recover damages, even if the offender had been convicted of the crime.

RACE/ETHNICITY AND VICTIMIZATION

This entry describes the empirical relationship between governmental statistics on crime victimization and the federally defined categories of race and ethnicity. Extant research suggests that criminal victimization in the United States varies with regard to officially established racial and ethnic categories in much the same way as with other issues such as employment, housing, income, wealth, health and education, and criminal offending. Official statistics collected by various federal agencies indicate that Blacks/African Americans and Hispanics are disproportionately overrepresented as victims of both violent and property crimes.

Definitions of Race/Ethnicity

The concept of *race* has generated considerable debate throughout our history. Definitions have ranged from a distinct objective biological taxonomy to the more social-cognitive approach. The latter approach understands race as a flexible and political social-cultural construct that treats physical differences as socially or culturally meaningful distinctions within and across historical contexts.

In the history of the United States, this racialization of the population was originally accomplished by dichotomizing citizens into categories of “White/Nonwhite” (i.e., English/non-English). After considerable iterations during the past 300 or 400 years (e.g., Asian Indians were considered as “Hindus”

in censuses from 1920 to 1940, as “White” from 1950 to 1970, and as “Asians or Pacific Islanders” in 1980 and 1990), the U.S. government through the Office of Management and Budget (OMB) now recognizes a minimum of five nonscientific categories for race: *American Indian or Alaska Native, Asian, Black or African American, Native Hawaiian or Other Pacific Islander*, and *White*. In addition, respondents can select *one or more* of these racial categories to allow for multiracial self-identification. As of January 1, 2003, all current federal surveys must comply with the above 1997 revisions.

The concept of *ethnicity* typically refers to differences across groups in the form of cultural factors, such as language, religion, and nationality. Ethnicity is best defined as existing when a group of individuals are perceived by others as culturally different, while the group also perceives itself as culturally different and expresses these differences through shared cultural activities.

The federal government in Public Law 94-311 of June 16, 1976, established the necessity for the collection of information on ethnicity with regard to persons of Spanish origin or descent. Except for the 1930 census where “Mexican” was designated as a racial category, prior to 1980, those of Spanish origin and descent were generally categorized as “White.”

As adopted on May 12, 1977, in *Race and Ethnic Standards for Federal Statistics and Administrative Reporting*, the bifurcated categorization of ethnicity of Hispanic (a person of Mexican, Puerto Rican, Cuban, Central or South American, or other Spanish culture or origin, regardless of

race) and non-Hispanic was initiated. This practice was modified in October 1997 with the requirement that ethnicity be represented by the minimum categories of *Hispanic or Latino* and *Not Hispanic or Latino* with no changes necessary to the definition.

Criminal Victimization Data Sources

Criminal victimization in the United States is principally examined by the Bureau of Justice Statistics (BJS) through the National Crime Victimization Survey (NCVS). Information on homicide victimization is collected by the Supplementary Homicide Reports (SHR) of the Federal Bureau of Investigation (FBI). The first national victimization survey in the late 1960s was a pilot study that examined 10,000 households and was conducted by the National Opinion Research Center at the behest of the President's Commission on Law Enforcement and Administration of Justice.

In 1972, the National Crime Survey was instituted but was redesigned and renamed the NCVS in 1992. The survey publishes trend data on criminal victimizations (1972–2006) for the population as a whole based on a varying nationally representative sample of households. In 2003, the NCVS complied with the 1997 OMB guidelines for collecting data on race and ethnicity as part of government surveys, and it used the following racial categories: White only, Black only, other race only (American Indian, Alaska Native, Asian, and Pacific Islander if only one of these races is given), and two or more races (all persons of any race indicating two or more races). In regard to ethnicity, individuals are now asked directly if they are Spanish, Hispanic, or Latino. This self-identification of whether they are of Hispanic ethnicity is asked before being questioned about their race.

The FBI's SHR initiated in the 1960s collects data on murder and non-negligent manslaughter. Authorized by Title 28, Section 534, of the U.S. Code, these data rely on law enforcement agency submissions and include approximately 91% of homicides reported in the Uniform Crimes Reporting (UCR) Program and are often weighted to account for this discrepancy. Data in which a victim's death is caused by negligence, suicide, or accident; justifiable homicides; and attempts to murder are not included or are independently analyzed.

Race/Ethnicity and Violent Victimization

NCVS estimates of violent crime in 2006 indicate that the rates vary with racial categories. The ratio of White to Black violent victimization is 1 to 1.38, whereas the ratio of White to other races (American Indian, Eskimo, and Asian, Pacific Islander) is 1 to 0.79. When Whites are compared with the category of "Two or more races," the rates are 23.3 to 66.3 per 1,000 persons 12 years and older, which is a ratio of 1 to 2.85. Although the 2006 survey rates are not comparable because of methodological changes, the patterns noted in 2006 are similar to patterns exhibited in prior years. Estimates indicate that Hispanics report a slightly higher violent victimization rate compared with Non-Hispanics (27.7 to 24.2, respectively).

In 2006, SHR indicated that most of the 14,990 murder victims were Black (7,421). Whites represented approximately 46%, whereas "Other races" made up 2.7% of murder victims. In about 1.4% of the cases, the race of the victim was "unknown."

When homicide, rape, robbery, and aggravated assault victimizations are combined, BJS (2008) reports that adjusted rates reflect since 1993 a ratio of Black to White serious violent victimization from a low in 2001 of 1.51:1 to a high of 2.09:1 in 2005. Trend data with regard to homicide victimization rates per 100,000 were highest in 1993, when the Black rate was 38.7, whereas the White rate was 5.3 and the "Other" rate was 5.5. From this point until 2005, rates for all three groups declined with a 2005 rate of 20.6 for Blacks, 3.3 for Whites, and 2.5 for "Other." Despite the decline, the rate of Black homicide victimization is disproportionately higher than the rates of both Whites and "Other."

Race/Ethnicity and Property Victimization

As is the case with violent victimization, property crimes tend to vary with the race of the head of the household. The rate of property victimization in 2006 was higher for Black households (185.6 per 1,000 households) relative to a rate of 156.7 for White households (1.18 to 1). "Other races" reported a lower rate (137.7) than both Whites and Blacks. The newly created racial category of "Two or more races" had the highest rate at 254.3 per 1,000 households.

Of the estimated 18,915,740 property crimes in 2006, approximately 16,247,000 were reported by Non-Hispanics. However, the rate of property victimization for Hispanic households was 211.7 compared to a rate of 154.7 for Non-Hispanics. This pattern held for all categories of property crime victimization with the exception of "completed theft less than \$50" (rate of 31.2 for Hispanics and 32.7 for Non-Hispanics).

Race/Ethnicity and Bias-Motivated Victimization

The FBI and NCVS also collect data on hate crimes. In the late 1970s, lawmakers responded to a perceived escalation in hate- or bias-motivated crime. Recognizing the aggravated nature and potential for social disruption when violence is motivated by bigotry, the passage of federal hate crime legislation treated bias-motivated offenses as a special class with enhanced penalties.

Hate crime refers to a criminal act committed against persons or property that is motivated by an offender's bias against the victim's race, ethnicity, religion, sexual orientation, or disability. An ordinary crime is classified as a hate crime when offenders select victims on the basis of a characteristic or affiliation and announce their motives either verbally or with recognizable symbols of group prejudice.

The Hate Crimes Statistics Act of 1990 authorized the FBI UCR Program to collect national data on bias-motivated crimes reported to police. The NCVS provides another source of national data on hate crime victimizations. Primary sources of hate crime data are summarized in the annual UCR Program publications of *Hate Crime Statistics* and the BJS supplemental report on *Hate Crimes Reported by Police and Victims*.

The UCR Program collects data on single-bias and multiple-bias hate crimes. In 2006, participating law enforcement agencies reported 7,722 hate crime incidents involving 9,080 offenses. Hate crimes require that one or more perpetrator(s) commit crime(s) violence against a person or place the victim in reasonable fear of physical injury. Corroborating evidence of the offender's intention or prejudice is required for hate crime designations. For example, derogatory language used by the offender in crimes of racial or ethnic intimidation and violence are needed to classify victimizations

as hate crimes. In cases involving the destruction, damage, or vandalism of property, hate symbols and messages would provide supporting evidence of bias.

An analysis of single-bias hate crimes offenses in 2006 indicates that 52.2% were motivated by racial bias relative to 13.6% that were motivated by an ethnic or national origin prejudice. Of the 4,737 racially biased incidents reported to law enforcement agencies, 66.2% were motivated by an anti-Black bias, whereas 21.3% were motivated by anti-White sentiments. With regard to the 1,233 offenses committed based on perceived ethnic/national origin of the victim, 62.3% were directed at Hispanic victims, whereas 37.6% targeted victims of other ethnic/national origins.

The BJS report, *Crime in the United States*, from 2006 indicates that most hate-motivated crimes were against persons (60%), whereas about 39.4% were crimes against property. Bias-motivated destruction/damage/vandalism of property constituted 31.1% of all hate crime offenses. Of the hate-motivated offenses against persons, 46% were intimidation, 31.9% were simple assaults, 21.6% were aggravated assaults, and 0.2% were homicides and/or forcible rapes.

Crime in the United States indicates that most (81.1%) of the 3,593 hate-motivated property crimes were acts of destruction, damage, or vandalism. The remaining property offenses (19%) consisted of burglary, larceny-theft, motor vehicle theft, arson, and other crimes.

RAPE

The original common law definition of rape in the United States was unlawful carnal knowledge of a woman by force and against her will. By definition, only a male could perpetrate rape and only females could be victimized by rape. This early definition also limited rape to penile penetration of the vagina. Under the common law, a husband was exempt from being charged with rape against his wife.

Throughout the mid-1960s and 1970s, women and victim advocates called for rape law reform and state legislatures began to revise rape statutes. Today, rape statutes include males and females as both possible perpetrators and victims. In most states, other forms of penetration (e.g., anal) have been included in revisions and the marital exemption has been repealed. Most states also ended the requirement that the alleged rape victim produce corroborating evidence to the crime.

Rape occurs when certain legal requirements are met, as set forth by the state where the event took place. Rape involves nonconsensual contact between the penis and the vulva or penetration of the anus, however slight; contact between the mouth and the penis, vulva, or anus; or penetration of the genital or anal opening of another person with a finger, hand, or other object (e.g., bottle or gun). Contact or penetration must be achieved without the victim's consent or involve a victim who cannot consent or refuse. Inability to consent to sexual activity

could occur because of age, illness, disability, being asleep, or the influence of alcohol or other drugs. Inability to refuse could result from the use of physical force (e.g., a weapon or bodily weapon such as hands) or threat to use force.

A typology can guide the classification of conditions of rape based on the victim's inability to provide consent to sexual contact or intercourse. Forcible rape involves penetration that occurs when an offender uses or threatens to use physical force. Physical force may involve holding the victim down or other forms of violence (e.g., grabbing, hitting, and slapping). Incapacitated rape occurs when the victim is not capable of consenting because of the effects of alcohol or drugs or is otherwise incapacitated, such as being unconscious or asleep.

Incapacitated rape also can be classified into drug-facilitated rape, alcohol and/or other drug-enabled rape, and other incapacitated rape. Drug-facilitated rape occurs when a victim cannot provide consent after deliberately being given alcohol, a drug, or other intoxicant without the victim's knowledge or consent. Consumption can be achieved surreptitiously or deceptively; he or she unknowingly consumes alcohol, a drug, or other intoxicant that inhibits the victim's ability to consent. Accounts of offenders "slipping" a drug, such as Rohypnol (flunitrazepam, also commonly known as the date rape drug) or GHB (gamma hydroxybutyric acid), into a victim's beverage fall into this category. Alcohol and/or other drug-enabled rape occurs when the victim cannot consent because of voluntary or self-induced consumption of alcohol, a drug, or other intoxicant. Other incapacitated rape happens when the victim is asleep or unconscious for reasons other than the use of alcohol, a drug, or other intoxicant.

One form of rape that does not involve force is statutory rape. Statutory rape occurs when a victim is under the legal age of consent and, as a result, cannot engage in consensual sex. The current minimum age of consent ranges from 14 to 18 years of age, depending on the state. In some states, individuals under the age of consent are legally unable to consent to sexual contact or intercourse; therefore, any sexual acts would be illegal. Some states have laws that are age-graded—the difference in ages between the two individuals dictates whether the action is considered statutory rape.

Incidence and Prevalence

Numerous data sources can be used to determine the incidence (the proportion of incidents) and prevalence (the proportion of victims) of rape. There are two annual sources of rape statistics in the United States: (1) the Uniform Crime Reporting (UCR) Program and (2) the National Crime Victimization Survey (NCVS). The UCR Program is a measure of the crimes reported to and recorded by law enforcement. Each year, police departments voluntarily compile their local crime reports and submit them to the Federal Bureau of Investigation, which then annually publishes *Crime in the United States*. One of the crimes measured by the UCR Program is forcible rape. Forcible rape, as defined in the UCR Program, is the carnal knowledge of a female forcibly and against her will. In 2007, 90,427 forcible rapes were estimated to be known to the police, which results in a rape rate of 59.1 offenses per 100,000 female inhabitants of the United States.

Rape typically goes unreported to the police. A more accurate estimate of the extent of rape has been determined via self-report surveys that ask a sample of respondents about their victimization experiences. The NCVS is a survey of households that asks individuals about their victimization experiences. According to the NCVS in 2007, there were 248,300 rapes and sexual assaults, with a rate of 1.0 per 1,000 persons 12 years and older.

Government agencies in the United States, such as the Centers for Disease Control and Prevention and the National Institute of Justice, have periodically funded national victimization studies. The National Violence Against Women Survey (NVAWS) reported that approximately 17% of women and 3% of men have experienced at least one rape during their lifetime. In the mid-2000s, Dean Kilpatrick and his colleagues developed a national study of drug-facilitated, incapacitated, and forcible rape. Their findings indicate that 18% of women have been raped during their lifetime, with 14.5% having experienced forcible rape and 5% having experienced drug-facilitated or incapacitated rape.

Another source of the scope of rape can be found in studies of college women. The National College Women Sexual Victimization (NCWSV) study reported that about 5% of college women

are raped, which may seem to be a small percentage until the college career is considered. When this statistic is extrapolated, between one fifth and one quarter of college women experience forcible rape during the course of their undergraduate college career, which on average lasts 5 years.

Repeat Rape

Research shows that many women experience more than one rape during their lifetime, either as a child or as an adult. Prior sexual victimization is a strong predictor of future sexual victimization, including rape. This recurrence of sexual victimization can occur across different developmental time periods (i.e., once in childhood and again in adulthood) or within the same developmental time period (twice during adulthood).

Leah Daigle and colleagues reported that women who were raped in the previous 12-month period averaged 2.9 rapes, whereas men averaged 1.2 rapes. Research from their NCWSV study has shown that 23% of women were repeated rape victims during the course of approximately 7 months. They also reported that repeat rape victims experience a disproportionate amount of all rapes that occur; slightly less than one fourth of the repeat rape victims experienced close to 40% of all the rapes. Subsequent rapes are likely to happen fairly soon after the initial rape. In fact, 48% of the subsequent rapes happen within the same month as the initial rape.

Rape Rates Over Time

The UCR Program estimates of forcible rape indicate that rape rates peaked during early 1990s (42.8 per 100,000 inhabitants in 1992) and steadily declined throughout the remaining 1990s and into the new decade (30.0 per 100,000 inhabitants in 2007). From 1998 to 2007, estimated rape rates decreased 2.9%, with a 3.7% decline from 2003 to 2007.

In 1995, the NCVS estimates show that rape rates were at or near a 23-year low; rape rates for 1995 were significantly lower than the adjusted rates for 1973. Rape rates have continued to decrease from 2.5 per 1,000 persons 12 years and older in 1993 to less than 1 per 1,000 persons 12 years and older in 2005. From 1993 to 2001, the NCVS rape rate decreased by 62.5%.

Measuring How Much Rape Occurs

One of the most controversial topics with the study of rape is counting who experienced rape victimization and who did not. The UCR Program can be used as an indication of the amount of rape that becomes known to the police in a given year. The UCR Program is notorious for its underestimating the amount of rape, mainly because many women do not report being raped to the police.

To glean a more valid estimate of the extent to which rape occurs, others have developed and relied on self-report surveys. Behaviorally specific questions that are based on legal definitions of rape are used in survey questions to obtain a valid measure of rape victimization. For example, descriptive language is used to describe acts that constitute rape. Beginning with Diane Russell's work in the early 1980s, others have used such questions. Mary Koss developed the Sexual Experiences Survey (SES) to measure the incidence of victimization and perpetration of rape and other forms of unwanted sexual experiences. Since rape consists of penetration, force, or threat of force that is achieved without consent, Koss included elements of each in her questions designed to measure rape. Penetration is measured by asking about sexual intercourse and sex acts (anal or oral intercourse or penetration by objects other than the penis). Force or threat of force was conceived as physical force such as twisting an arm and other examples of physical force. Finally, lack of consent was defined for the respondent as "when you didn't want to." Lack of consent also was measured by asking the respondent if she had sex when she did not want to because a man gave her alcohol or drugs. A woman is considered having experienced rape if she answered affirmatively to any of the three questions that measured rape. Koss and others noted sexual victimization researchers revised the SES in 2007 to include more behavioral specificity, to convert to gender neutrality, and to revise and update wording for assessing consent and alcohol-related incidents.

The SES has been widely used, and other national-level surveys such as the National Women's Study and the NVAWS also have used behaviorally specific questions to measure forcible rape. Another approach has been to use a two-stage measurement process such as the one used in

the NCVS. Respondents are asked a wide range of victimization screen questions with short behavioral-specific cues, including "forced or coerced," "sexual acts," and prompting with specific types of possible offenders (e.g., casual acquaintance or someone you know well). If an affirmative response to experiencing this behavior is given, the interviewer completes a detailed incident report. In an incident report, respondents are asked about the perpetrator's force or coercion and the degree of the behavior experienced (e.g., threatened, attempted, or completed). It is within the incident report that the type of rape, if any, gets classified. The NCWSV also used a two-stage measurement strategy modeled after the NCVS.

Characteristics of Rape

Injury

More than 20% of males and 30% of adult female rape victims in the NVAWS reported that the offender threatened to kill or harm them; only a small proportion of rape victims reported serious physical injury in addition to the rape. Rapes that occur in the context of a date or another existing relationship are less likely to result in serious physical injury than rapes perpetrated by a stranger. More than one third of rape victims in the NVAWS reported experiencing some form of physical assault in addition to the rape itself, most commonly being slapped or hit. During the rape, victims may experience trauma to their genitals or anus from the penetration or other physical injury, such as bruises, cuts, and scrapes. Even though several victims report being injured, only about one third of those who reported being injured sought medical treatment for those injuries. In a very small percentage of cases, the rape can result in death.

Weapon

Most rapists do not use a weapon during the incident, although if a weapon is used, it is most likely to be a firearm. Offenders are less likely to use other forms of weapons such as knives or other objects. NCVS data indicate that about one third of rapes and sexual assaults involve any weapon. Of the incidents in which the

offender did use a weapon, the offender used a handgun in one in five incidents and a knife in 5% of incidents.

Location

Most rapes occur in private settings (e.g., a residence). The NCVS reported that rapes were most commonly perpetrated while the victim was participating in leisure or other activities away from home or while asleep. The NCWSV study reported that a large proportion of college women who are raped were raped in living quarters, such as a dorm room or apartment.

Time of Day

Most rapes occur in the evening hours. Most of the sexual victimizations reported in the NCVS occurred between 6 p.m. and 6 a.m. For college women in the NCWSV study, more than half of rapes occurred after midnight, whereas few occurred during the day.

Alcohol and Drug Use

There is a strong correlation between alcohol and drug use and rape victimization and perpetration. In the NVAWS, almost two thirds of the women who were raped as adults indicated that the offender was under the influence of alcohol and/or drugs at the time of the incident. Drug and alcohol use is also not uncommon on the part of the victim. According to the NVAWS, almost 20% of women and 38% of the men raped as adults reportedly had used alcohol and/or drugs at the time of the victimization.

For college women, alcohol use has been reported as a risk factor for rape victimization, perhaps because of the party culture commonly associated with college campuses. Alcohol use has been identified as a general risk factor for college women being victimized. Women who drink more frequently are more likely to be sexually victimized than women who drink less frequently or not at all. A large number of studies of college students and young adults have reported that roughly half of all rapes experienced involved alcohol use voluntarily or unknowingly consumed by the perpetrator, the victim, or both.

Number of Perpetrators

Most rapes that occur are perpetrated by a single offender. In this way, rapes typically involve one offender and one victim. Multiple perpetrators sometimes do offend (e.g., gang rape), but these incidents are not the norm.

Who Is the Offender?

There is no single identifying characteristic of individuals who rape. Rapists can be anyone. Some patterns can be identified in terms of who is arrested for committing rapes and who is identified as being the offender via victim surveys. Arrest reports from the UCR Program indicate that most persons who are arrested for forcible rape are White males who are between the ages of 18 and 30 years old. Less than 2% of arrests for rape are made against females. Victim reports of the offender also reveal a similar pattern. According to the NCVS, most single-offender rapes are perpetrated by young, White males.

Even though rape is often thought of as a crime of violence in which a person is attacked in a dark, secluded place by a stranger, rapes are most commonly perpetrated by someone who is known to the victim. The NCVS consistently has reported that more than half of the offenders include friends, dating partners, and casual acquaintances; about 30% of offenders are strangers to the victim. Findings from the NVAWS support this victim-offender relationship pattern in that most rape victims know their rapist. Less than one quarter of rapes are perpetrated by a stranger. Females in the NVAWS reported being raped most commonly by a current or former intimate partner, whereas acquaintances were most likely to be the perpetrators of rapes of males. College women are also most likely to be raped by someone they know, most commonly a boyfriend, ex-boyfriend, classmate, friend, acquaintance, or co-worker.

Who Is the Victim?

Although rape can happen to anyone, some people are at greater risk than others. Across the life course, females are much more likely to experience rape than males. This is not to say that males are not raped; however, most rapes are perpetrated against females.

Young persons are more likely to be raped than older individuals. Females and males are at an increased risk of being raped when they are younger than 18 years old. More than half of female victims and almost three fourths of male victims in the NVAWS were raped for the first time before turning 18. Risk of first rape is next highest for individuals between the ages of 18 and 24 years. When all rapes were examined, women were equally likely to be raped before turning 18 as after. Males are more likely to be raped as a child (under the age of 12 years) than at any other stage in their lifetime. Women who are unmarried, who live in low-income families, who are unemployed, and who reside in metropolitan areas are more likely to experience rape than women who are not similarly situated.

Persons of certain race or ethnicity are more at risk than others of experiencing rape. Minority women and men are more likely to be raped than nonminorities. American Indian/Alaska Native women are more likely to experience rape than women from other types of background.

Responses to Rape

Resistance

Many victims have reported that they attempted to stop the incident from occurring or being completed by using resistance or self-protective action. Self-protective actions are typically categorized into one of four categories based on the amount of force involved and whether it was verbal or physical. Forceful physical self-protective actions are those that are active and aggressive, such as punching, biting, and scratching. Using a weapon to resist would also be considered forceful physical. Nonforceful physical self-protective actions are passive, such as fleeing or pulling away. Forceful verbal self-protective actions are active strategies that are employed to scare the offender or to get the attention of others. Yelling and screaming are examples of this type of self-protective action. Nonforceful verbal self-protective actions are nonaggressive verbal actions, which include pleading with, talking to, and begging the offender.

Generally, women employ at least one of these self-protective actions during a rape, with three

fourths of women having used self-protective actions during the course of a rape. Forceful actions, particularly those involving physical resistance, are most commonly used by rape victims. The type of self-protective action used is important because different types are effective at reducing the likelihood that a victim will be injured and/or that the incident will be completed. Research suggests that self-protective actions are most useful when they are in parity with the amount of force used by the offender. Since rape by definition involves force or the threat of force, forceful strategies are most associated with rape avoidance.

Acknowledgment of Rape

Research has shown that not all victims whose experience meets the legal definition of rape acknowledge that they are rape victims. For example, in the NCWSV study, less than half of the completed rape victims considered the incident to be a rape. Acknowledgment is important for several reasons. Persons who acknowledge that they have been raped may begin a process of healing and recovery, although there is not a consensus regarding the psychological benefit of acknowledgment. Acknowledged rape victims may seek help from outside sources such as their friends, family, or formal services. Persons who do not think they have suffered a rape are unlikely to report their victimization to the police, thus precluding arrest or prosecution of their offenders and being able to access other resources such as a victim-witness assistance program.

Reporting

Despite its seriousness and the harsh penalties associated with rape in our criminal justice system, rape is one of the most underreported victimizations. For college women, less than 5% of rapes are reported to the police. Victims in the community are also unlikely to come forward to the police about their rape. According to the NCVS, only about one third of rapes are reported to the police. Rape victims, however, typically disclose their experience to someone, even if it is not the police. College women overwhelmingly tell a friend about their rape. Family members and help-providers are also people victims talk to about their rape.

There are many reasons why rape victims do not make a formal report to the police. Victims from community samples indicate that most commonly they did not report to the police because the rape was a personal matter, they feared reprisal from the offender, they felt the police were biased, and they were unsure the incident was a crime or that harm was intended. Similar reasons have been given by college women.

Sexual Assault Response Team and Sexual Assault Nurse Examiners

Community outreach to rape victims can include the availability of a sexual assault response team (SART)—a coordinated multidisciplinary community, including law enforcement, victim advocates, and forensic nurses—to provide emotional and mental support; sometimes SARTs are located in rape crisis or women's centers. Sexual assault nurse examiners (SANEs) can perform a sexual assault forensic examination to detect physical oral, anal, and vaginal injuries that can be admitted into legal proceedings as evidence. Marilyn Sommers and her colleagues note the implications of SANE for the criminal justice system; research that has shown injury plays a significant role in a rape case from the victim's decision to report to law enforcement, to the prosecutor's decision to bring the case to court, to the arrest and conviction of the accused.

Effects of Rape

Rape victims often experience a range of negative effects from the incident. In addition to physical injury, rape victims often report experiencing emotional and psychological problems after the rape. Rape victims often experience elevated levels of anxiety and depression as well as report experiencing problems interacting socially. It is also not uncommon for rape victims to experience disturbances in their sexual functioning. Many victims find it difficult to be intimate, even within committed relationships, whereas others may increase their level of sexual activity. Victims may experience negative effects in terms of their worldview and of themselves. Being a rape victim may change the way in which persons view their own vulnerability in that they may no longer see themselves as impervious to victimization. They may also feel as

though they are not able to control what happens to them. Another common occurrence is victims blaming themselves for their own victimization. Instead of recognizing that the blame for their rape lies with the offender, rape victims often scrutinize their own behavior and take on the responsibility. Another psychological consequence of being raped can be posttraumatic stress disorder (PTSD).

As a result of the physical and psychological impact of rape, some victims seek assistance from mental health professionals. About one third of the women and one fourth of the men in the NVAWS who were raped received mental health counseling. Also, economic and social losses often accompany rape. About one tenth of rape victims report some form of economic loss because of their victimization. The NCVS shows that about 12% of victims reported loss of time from work. Of those rape victims, the majority missed between 1 and 5 days of work. The NVAWS also reveals that rape often carries consequences that impact everyday life. Loss of time in social and recreational activities, school, and volunteer work also sometimes occurs.

Rape Victims and the Criminal Justice System

Historically, rape victims have had a tenuous relationship with the criminal justice system. As noted, many rape victims do not report their experience to the police—sometimes because of their suspicion about how they will be treated by the police and the larger criminal justice system. This worry is likely not without basis, since accusations of rape were often met with open skepticism and disbelief. A reflection of this disbelief is observed in how rape victims were treated under the law and how conviction of the accused was difficult to achieve. A woman originally had to be able to show that she forcefully resisted her attacker to secure a conviction against her offender, but most states no longer require that a woman prove she physically rebuked the perpetrator.

In the past, rapes also had to be corroborated. Independent evidence had to be introduced into the case that corroborated the key elements of the woman's account of what transpired. Corroboration could include medical evidence, forensic evidence, physical injury, eyewitness testimony, testimony from someone who had promptly been told of the incident, and signs of struggle. What was problematic is that

many women do not experience serious physical injury, most rapes take place without third parties present, and physical evidence may be lacking. Corroboration laws also implicitly signal the victim that her testimony alone is not credible, which may further dissuade the victim from reporting the rape.

Since the 1970s, rape law reforms have been undertaken, and currently, many protections are afforded to rape victims in the criminal justice system, such as corroboration laws being redacted or relaxed. Rape shield laws are now in place to protect a woman during the course of a criminal trial. These laws generally prevent defense attorneys from using as evidence a woman's prior sexual conduct during the trial unless the woman and perpetrator had engaged in sexual conduct prior to the alleged incident or if she has obvious incentive to lie. These laws allow the judge to make admissibility determinations regarding the victim's past in a closed setting and provide the judge with legal justification for preventing such testimony. The name and identity of rape complainants are routinely kept out of the news, with many newspapers, radio stations, and television stations having policies that protect individuals from unwanted media exposure.

Other elements of the system have also been reformed to address the unique needs of rape victims. Many police departments train officers in how to interview victims of sexual assault and rape, as well as have specialized sex crime units. Many police departments also have Victim Assistance Programs that assist victims and their families as they navigate the criminal justice system. These types of programs are also often found within prosecutor's offices as are sex crimes units with specially trained lawyers.

Rape Prevention and Risk Reduction

Many rape prevention and risk reduction programs have been implemented, especially at post-secondary institutions that receive federal financial aid; for them, rape prevention programs are mandated by the Jeanne Clery Disclosure of Campus Security Policy and Campus Crime Statistics Act. It is not too surprising then that most of the few evaluations that have been completed have been conducted with college students.

These programs primarily focus on changing rape and rape-related attitudes, rape knowledge

and intended behavior, incidence of rape, rape empathy, and rape awareness behaviors. Linda Anderson and Susan Whitson's meta-analysis of 69 studies concluded that the latter two outcomes did not have average effects sizes that significantly differed from zero; all other outcomes had significant average effect sizes. Kimberly Lonsway and her colleagues argue that effective rape prevention takes place by changing men's behavior since they are the primary rape offenders, as well as by educating women as to how to deter rape through reducing an individual's vulnerability to high-risk situations.

Rape Prevention for Men

Only a small percentage of rape prevention programs target how men can prevent rape, and few evaluations of these programs exist. A few programs have demonstrated success in changing men's beliefs and attitudes regarding rape, but the lack of long-term stability of attitude changes is relatively unknown.

Risk Reduction Programs for Women

Education programs, especially those with a self-defense component, show some promise of reducing the risk of rape. Collectively these programs suggest three stages of resistance: (1) assess the situation as potentially dangerous, (2) acknowledge the situation as a potential rape, and (3) act with active resistance strategies. Such programs would include educating women how to recognize vulnerable situations and teaching skills about how to implement specific resistance techniques (e.g., forceful physical techniques).

Program for Both Sexes

One promising avenue for rape reduction is to focus on men and women as bystanders and as agents to change social norms in a peer culture that supports abusive language and behavior. Men and women engage in education and skills practice to teach them reactive interventions after a rape occurs and proactive interventions in high-risk situations such as friends who express sexist comments or try to take an unwilling or drunk person to a secluded location.

Few evaluations of bystander programs have been conducted, but the results to date are encouraging. Victoria Banyard and her colleagues provided the first

empirical evidence that a bystander intervention for sexual victimization prevention resulted in significant and sustained changes in knowledge, attitudes, and bystander behaviors in both men and women.

RAPE, ACQUAINTANCE AND DATE

Acquaintance rape and *date rape* are terms describing rape that occurs between people who know each other. In this entry, the term *rape* includes

nonconsensual sexual intercourse and other non-consensual sexual acts. Acquaintance and date rape are the most common forms of sexual victimization, and it is estimated that between 60% and 80% of rape victims know their rapists. Although these forms of rape have been brought closer to the forefront of societal issues since the 1980s, much controversy surrounds them. Most cases of acquaintance and date rape are never brought to the attention of the police, and even fewer are prosecuted. Some victims never seek emotional or psychological assistance in healing from a rape and frequently keep it a lifelong secret. One fact that research has established is that most victims of acquaintance and date rape are women, and most perpetrators of these crimes are male. Because of the high number of victimizations and the seriousness of the crime, acquaintance and date rape are salient issues in victimology and crime prevention.

Defining Acquaintance and Date Rape

Although the terms are used interchangeably, acquaintance and date rape represent two different relationships between the people involved in a rape. Acquaintance rape occurs between people who know each other, but who are not in a dating relationship. The people can be friends, co-workers, neighbors, schoolmates, or in other relationships that do not involve dating. Date rape occurs between people who are on a single date or who are in a dating relationship involving multiple dates. If the relationship has developed into a more serious commitment, then the term *intimate partner violence* tends to be used to define any type of violence that occurs within that relationship, including rape and other forms of sexual assault. Rape and sexual assault are frequently used in dating and intimate relationships by one person to gain or maintain power and control over the other person.

Anyone can be a victim of acquaintance and date rape; however, women are the most frequent victims, and men are the most frequent perpetrators of these crimes. This does not preclude males from being victims and females from being perpetrators. It also does not preclude acquaintance and date rape from happening in same-sex relationships. However, the female victim-male perpetrator dyad in the crime is the most commonly reported. Some age groups of women are at a

higher risk for victimization than are others. In particular, younger women, ages 12 to 24 years, are a high-risk group. This risk is partly because of their life activities, which for this age group includes dating and socializing in a variety of settings, and their perceived vulnerability by offenders. As a result, acquaintance rape prevention education programs in junior high schools, high schools, and colleges frequently emphasize personal safety in addition to having healthy relationships.

Prevalence and Incidence

Although the estimates vary, it is accepted that acquaintance and date rape have impacted millions of people over their lifetimes. Estimates of the prevalence and incidence of acquaintance and date rape come from many sources, including the federal government, state governments, and studies conducted by academic researchers. The prevalence of rape is the number of people victimized within a given time frame. The incidence of rape is the number of total incidents experienced by all victims within a given time frame. The incidence of rape is higher than the prevalence because some people are victimized multiple times, usually by the same person. *The Ms. Report on Recognizing, Fighting, and Surviving Date and Acquaintance Rape* conducted by Mary Koss is generally recognized as the first major study examining date and acquaintance rape in detail. It is from this study that the oft-cited "one in four" statistic emerged—one in four women in this study had been victims of a rape or an attempted rape. This statistical estimate of acquaintance and date rape has remained steady through many years of research. This study also revealed that more than 80% of these women knew the person who raped or attempted to rape them, which is another statistic that has been consistent across many studies.

Estimates of the prevalence and incidence of rape differ across studies because of the varying methodology in gathering the information. Some studies ask general questions regarding rape experiences, whereas other studies ask more specific questions. Studies with specific questions tend to have higher estimates of the prevalence and incidence of these forms of rape because people do not have to self-identify as rape victims. Self-identification occurs when people affirm they have

been raped based on their views of what acts constitute rape. More specific questions address a variety of sexual activities that may be illegal but that person being interviewed may not identify as rape or otherwise illegal. Some people do not identify as rape victims because their experience does not match their perception of “real rape,” which is frequently similar to the stereotypical view of rape described later in this entry. As a consequence, many people who were raped by a date or an acquaintance would likely answer negatively to this question because they may think rape only happens by a stranger.

A Societal Issue

Rape has always occurred in society, but it was not openly discussed until the 1970s. Anti-rape movements began to bring attention to the way victims were treated within the criminal justice system, and educational efforts began to focus on dispelling myths about rape. Many of these myths stem from gender roles and stereotypes that exist in society and are directly related to acquaintance and date rape. Gender roles and stereotypes are beliefs about how males and females should act. They are impressed on people beginning at birth—girls traditionally wear pink clothing and are encouraged to play with dolls; boys traditionally wear blue clothing and are encouraged to play with trucks. Many of these gender roles and accompanying rape myths are about expected sexual behaviors. One such gender stereotype is that women are supposed to be sexually discrete, whereas men should be sexually aggressive. Related, women are supposed to maintain their sexual integrity until they are married, whereas men are expected to engage in premarital sex. Women are also taught to be polite and to avoid conflict, whereas males are encouraged to pursue and solve problems aggressively. These gender roles and rape myths contribute to creating circumstances where people are at risk for being raped and to rape.

Despite educational efforts, society still tends to have a stereotypical view of rape as something that happens between strangers, and this is considered “real rape.” This view generally consists of an unknown person, a male stranger, who attacks an unsuspecting woman. This view persists even though it has been consistently demonstrated that most

people who are raped or otherwise sexually assaulted know their attacker(s). Another myth that society believes in is that victims of rape will suffer extreme injuries such as broken bones and cuts because of the use of physical force by the rapist that is in response to victim resistance. However, most victims are not physically injured, and although most resist, fear usually results in compliance and submission to the will of the rapist. The result of these faulty beliefs is that when acquaintance and date rapes do not fit the scenario, doubt is cast on the credibility of the victim and the accusation of rape.

At the core of the discussion about acquaintance and date rape is the issue of consent. Many times these rapes are referred to as “he said, she said” cases because one person says that the sexual activity was not consensual, whereas the other person says the sexual activity was consensual. Acquaintance and date rape are often viewed by society as instances of miscommunication between sexual partners, suggesting that one or both people involved did not accurately or clearly communicate their desires with regard to which sexual activities were consensual and which were not consensual. In understanding acquaintance and date rape, it is helpful to distinguish among the terms *compliance*, *submission*, and *consent*. Compliance means to do something even if a person does not agree with the activity, submitting means not having enough power or strength to resist, and consenting means actively agreeing to participate in an activity. A rape victim’s compliance with or submission to sexual acts is sometimes confused with consent and is used to place blame on the victim for the rape. Victims may comply and submit to nonconsensual sexual activity out of fear of what will happen to them if they do not.

Even more frequently, acquaintance and date rape is viewed by society as an instance of a woman regretting consensual activity. This perception paints women as vindictive, fickle, and/or unwilling or unable to handle the consequences of having sex. Women are often accused of “crying rape” in an effort to protect their reputations and to avoid being labeled as sexually promiscuous. These perceptions are related to the gender norms and stereotypes that serve to pigeonhole men and women into roles created by the larger society, and make the prevention and prosecution of acquaintance and date rape difficult.

The Criminal Justice System

Victims of acquaintance and date rape usually do not tell anyone they have been assaulted. Those who do will usually confide first in a friend or family member and rarely report the crime to the police. Very few acquaintance and date rapes are prosecuted because of the difficulty of proving them in court when the only evidence is often testimony from the victim and the suspect. Sometimes victims of acquaintance and date rape are not treated well by the police and other components of the criminal justice system. A victim's character is often called into question during trials, and defense attorneys attempt to discredit victims by discussing their sexual histories. One goal of the anti-rape movement is to improve the treatment of women who report their rapes. One accomplishment was the passing of rape shield laws, which prohibits certain types of testimony from being entered into evidence at trial. Disallowed information includes the victim's sexual history unless that history includes prior consensual sexual activity with the person being accused of rape. Although rape shield laws protect victims in many instances, they are not foolproof, and their use cannot be guaranteed. It is this negative treatment that has led to the criminal justice experience being called a "second rape" for victims.

Impact on Victims

The impact of acquaintance and date rape on victims reaches far beyond the event itself, and these feelings and experiences are collectively referred to as Rape Trauma Syndrome. During a rape, victims may feel fear that they are going to die, feel out of control of their bodies, and feel shock and disbelief that someone they trusted could hurt them in such a way. Many victims feel they contributed to the rape through their behavior, making it their fault. For example, victims who have been drinking alcohol may feel this is the reason they were assaulted. Victims may also feel shame, embarrassment, confusion, anxiety, guilt, and humiliation. These feelings impact the decision to tell someone else about the rape, and whether to report to the police and go forward with criminal charges.

Victims sometimes have fears that they will be raped again, and they may take steps to prevent this from happening such as purchasing a handgun

or taking self-defense classes. Victims may have bad dreams, difficulty eating, problems sleeping, and may be afraid to be alone. Some victims have difficulty functioning at work or at school. Personal relationships can be deeply affected by rape. Victims of acquaintance and date rape may have difficulty trusting other people, particularly men that they know, and may experience problems with having consensual sexual relations. Some victims will use alcohol or drugs to cope with their feelings, and sometimes they will self-injure themselves. Victims of acquaintance and date rape should be encouraged to seek professional assistance in recovering from the trauma.

There can be social ramifications for victims of acquaintance and date rape. High-school and college students who are raped may be ostracized from their peer groups. It is not uncommon for people to spread rumors about the victim in an effort to protect the perpetrator. It is difficult for people to believe that someone they know could be a rapist, and it is easier to blame the victim for what happened. These ramifications can happen at a victim's place of employment as well. Sometimes victims transfer schools or find a new job to avoid the negative atmosphere.

Alcohol and Drug Use

Alcohol is a common factor in acquaintance and date rapes, and it is frequently used by rapists to justify their actions and blame victims for the rape. Rapists can claim that they are not responsible for their actions because they were intoxicated. They can also use the victim's alcohol use as a way to call her character into question. Sometimes acquaintance and date rapists use drugs to facilitate the rape. Gamma-hydroxybutyrate (GHB) rohypnol, ketamine, and other drugs with sedative properties cause symptoms similar to intoxication, which can make it difficult for a person to know whether she has been drugged, particularly if she has also been drinking. In addition, the effects of the drugs happen quickly, and there is little time to seek help once the victim realizes she has been drugged. The drugs leave little toxicology evidence behind and cause memory loss. These characteristics make them attractive to sex offenders. It is illegal to have sex with someone who is intoxicated or under the influence of drugs, because an

intoxicated person cannot legally give consent to sexual intercourse or other sexual activity.

Prevention

Unlike other crimes that can sometimes be prevented through altering the environment (such as removing shrubbery from around the windows or installing exterior lighting around a house to reduce the risk of burglary), the prevention of acquaintance and date rape relies largely on shifting cultural values and norms about sexual violence. As such, the prevention of acquaintance and date rape is largely accomplished through educational programs for both females and males. These programs encourage adopting belief systems that do not support sexual violence, provide information about the characteristics of healthy and unhealthy relationships, and encourage open communication and communicating sexual boundaries with dating and intimate partners. Other programs emphasize personal safety, including recognizing the warning signs of a potentially physically and sexually abusive relationship, encouraging the use of the buddy system when attending social functions, limiting alcohol consumption, and discouraging the use of illegal drugs.

Internet dating sites, social networking sites, and chat rooms are now prominent media that people use for dating and socializing. In many ways, the Internet has replaced the "bar scene" of prior generations as a primary means of meeting new people and advancing a person's romantic and social lives. People can use the Internet without leaving their homes, and they can screen multiple people at one time to determine whom they want to meet. However, the anonymity of the Internet has worked to create its own form of risk when dating and socializing using these media. A person can create an identity that is completely fictional or at least not entirely accurate. As a result, several cases of acquaintance and date rape have occurred through meeting via the Internet. This information is frequently incorporated into rape education programs.

This entry has discussed many aspects of acquaintance and date rape, including its extent, its impact on victims, its place as a societal issue, and its prevention. As stated, the extent of acquaintance and date rape makes it a prominent issue for victimology and

crime prevention. However, the controversy surrounding these crimes, and their private nature, also makes them difficult to address. In a society that tends to excuse and sometimes condone sexual violence, the prevention of acquaintance and date rape is difficult. As a result, acquaintance and date rape are two crimes that will likely be at the forefront of the crime prevention and victimology movement for many years to come.

RAPE, MARITAL

Marital rape is forced, nonconsensual sex where the perpetrator is the victim's spouse. The term *marital rape* is used interchangeably with *wife rape* and *spousal rape* and often applies to cohabiting intimate partners as well as to legally married couples. Marital rape was criminalized in all of the United States as of 1993 with the deletion in the criminal statutes of all states of the spousal exemption, which defined rape as

forced intercourse without the consent of the woman other than one's wife. The spousal exemption remains in effect in most non-Western countries. Of all forms of violence against women, marital rape is the least likely to be criminally prosecuted or socially sanctioned. It is not recognized as a social problem in most of the world, research on this form of violence is limited, and its victims have few services available to them. This entry provides an overview of the historical and legal context of marital rape, prevalence information, research on marital rape attitudes and experiences, as well as on intervention and prevention approaches.

Historical and Legal Context

The legality of marital rape in Western societies can be traced to early laws regarding marriage and rape. Roman law of the 8th century codified the status of wives as the property of their husbands. Rape laws were originally framed as property law, focused not on protecting women's bodily integrity but on protecting men's property (wives and daughters) from defilement by other men. Marital rape was even more explicitly codified in British Common Law in the 17th century. British jurist Sir Matthew Hale made the case for the marital rape exemption in the *History of the Pleas of the Crown* arguing that "the husband cannot be guilty of a rape committed by himself upon his lawful wife, for by their mutual matrimonial consent and contract the wife hath given up herself in this kind unto her husband which she cannot retract." Hale's doctrine was incorporated into laws around the English-speaking world and became a foundation of U.S. rape statutes. Furthermore, the legal principle of matrimonial unity ensured that wives had no legal recourse against their husbands. As American legal scholar William Blackstone wrote, as the new nation was being established, the husband and wife are considered one person under the law, meaning that the very being or legal existence of the woman is suspended in marriage. The legal institutionalization of wives' permanent consent to sex and their lack of legal recourse against their husbands led marital rape researchers David Finkelhor and Kersti Yllo to assert that the marriage license was, in effect, a license to rape.

In the second half of the 19th century, the women's movement in the United States opposed the legal oppression of marriage and obligatory sex. The first wave of feminists not only challenged wives' lack of independent legal rights and sexual autonomy but also what they regarded as compulsory maternity. In the absence of safe, reliable, legal contraception and abortion, forced sex and forced child-bearing went hand in hand. Subsequent changes to marital property law did not include the elimination of the spousal exemption, and forced sex in marriage remained a husband's right.

It was not until the second wave of the American women's movement that marital rape again became a controversial topic of public debate. Susan Brownmiller and Del Martin both publicly challenged the rape laws in the mid-1970s, and Diana Russell was the first scholar to conduct comprehensive research on rape in marriage. Grassroots feminist organizations around the country, led by activist Laura X, launched political and legal battles to eliminate the spousal exemption from the statutes of all 50 states. It took nearly two decades of activism to change the laws, but on July 5, 1993, North Carolina became the last state to criminalize rape in marriage. Although marital rape is a crime throughout the United States, currently about half of the states maintain some exemptions from prosecution. Most commonly, a husband is exempted when he does not have to use physical force to have intercourse because his wife is legally unable to consent (because she is mentally or physically impaired, unconscious, or asleep). Efforts are still underway to eliminate all spousal exemptions.

The criminalization of rape in marriage has not resulted in the avalanche of criminal cases that was predicted by those who fought to maintain the spousal exemption. In fact, marital rape remains the most underreported category of sexual assault, and the number of successful prosecutions remains small. Two of the most famous marital rape trials both resulted in acquittals. The Rideout case in Oregon in 1978 was the first in which a husband was tried for rape. The Bobbitt case in Virginia in 1994 achieved notoriety because John Wayne Bobbitt was prosecuted for marital rape after his wife cut off his penis with a kitchen knife. In both cases, there was evidence of prior domestic violence but no conviction on the sexual assault

charge. Overall, marital rape convictions are most likely when sexual assault charges are brought concurrently with other serious charges such as battery, kidnapping, and attempted murder.

Prevalence

The prevalence rates of marital rape indicate that there is a global epidemic of forced sex perpetrated by intimate partners. Diana Russell's ground-breaking research in the 1980s was the first to document high rates of rape in marriage and cohabiting relationships and was followed by Finkelhor and Yllo's study. The researchers surveyed representative samples of women in the San Francisco Bay area and Boston and estimated that 10% to 14% of married women have experienced forced sex by their partner. More recently, the National Violence Against Women Survey, conducted in 1998, found a 7.7% rate of sexual assault by an intimate partner, which leads to the estimate that in the United States more than seven million women have been raped by their partners. A 2005 World Health Organization (WHO) study documented rates of sexual violence by a partner that ranged from less than 10% in urban Japan to more than 50% in rural Bangladesh and Ethiopia.

Smaller scale studies have also addressed the prevalence of marital rape. Several clinical studies of battered women have indicated that between one third and one half of women who have been physically abused report that they were also sexually assaulted by their partner at least once during the relationship. Other studies found that about one quarter were forced to have sex only once or twice, whereas more than 50% were forced 20 or more times in the course of the relationship. Research on men who sexually abuse their partners is limited. One study of 229 men enrolled in a batterers' intervention program found that 53% admitted to activities that are legally defined as rape or sexual assault, even though only 8% answered affirmatively to the question "Have you ever sexually abused your partner?" An important limitation of these studies is that they focus on women who have been physically battered. A study of a nonrepresentative sample of 50 marital rape victims found that 40% had not experienced physical violence beyond the force used to complete the rape.

Marital Rape Attitudes

In comparison with the very limited amount of research focused on actual victims and perpetrators of forced sex in marriage, perceptions of marital rape have been the subject of numerous studies. Studies have typically presented various vignettes describing sexual assaults to subjects (most often college students). By varying certain descriptors in the scenarios, such as the victim-perpetrator relationship, involvement of alcohol, or the victim's dress, researchers assess the impact of many relevant variables that shape perception and attribution. Although the body of research on the perception of rape is extensive, studies that directly address marital rape represent a small subset.

Overall, the research provides evidence that marital rape is viewed as less serious and less damaging both physically and emotionally than other forms of rape. Numerous studies find that the relationship between the perpetrator and the victim significantly affects perceptions; as acquaintance-ship and intimacy in the relationship increase, assessment of the trauma and seriousness of the assault decrease. The stereotypical stranger rape is perceived as more grave than an acquaintance rape, which is regarded as more serious than a marital rape, even when descriptions of the acts of sexual assaults themselves and injury resulting remain constant. Wives who are raped are more likely to be blamed for the attack than unmarried victims.

The most significant characteristic of research subjects to affect rape attitudes is gender, with men consistently endorsing general rape myths more strongly than women. When research focused specifically on rape in marriage, the male-female disparity in perceptions is even greater. Early studies about the legality of marital rape found women much more likely to favor the removal of the spousal exemption than men. Other studies have found women more likely than men to consider marital rape no different than other types of rape. Research on the impact of respondents' age on perceptions has been mixed. However, recent studies have found, overall, less support for rape myths than those conducted decades ago.

Studies of marital rape attitudes have documented that sexual assault within marriage is not taken as seriously as other forms of rape. However, overall, rape myths do seem to be on the decline.

It is important to note, though, that most research on perceptions and attributions regarding rape has been conducted using college student samples. How other groups, especially of different class and racial/ethnic backgrounds, think about rape in marriage is largely unknown. Moreover, social-psychological research has documented the lack of consistency between stated attitudes and behavior. It is not known whether stated views of marital rape are actually indicative of actions toward perpetrators or victims.

The Experience of Marital Rape

Only a few scholars have extensively studied the experiences of women who were raped by their husbands. The studies presented in Russell's book *Rape in Marriage*, Finkelhor and Yllo's *License to Rape*, and Bergen's *Wife Rape* are all based on in-depth interviews with victims and provide detailed documentation of the sexual abuse perpetrated by husbands and cohabiting intimate partners. This research details the range of experiences (including forced oral and anal as well as vaginal sex and penetration with objects) that come under the heading of marital rape. Finkelhor and Yllo developed a typology that identifies three types of marital rape: battering rapes, force-only rapes, and obsessive (also referred to as sadistic) rapes. Other research has confirmed these basic types, although many cases share characteristics of more than one type.

Battering Rapes

Rapes that occur in the context of physical abuse within marriages and cohabiting relationships are the most likely to come to the attention of researchers as well as service providers and the criminal justice system. As noted, it is estimated that one third to one half of battered women are also forced to have sex. Battering rapes are characterized first and foremost by the high level of physical violence that often precedes or accompanies the forced sex.

The men who commit battering rapes are primarily motivated by anger according to Nicholas Groth, who has worked extensively with rapists. Their goal is to express hostility toward women and to hurt and humiliate their victims, and they

do so by using far more physical violence than necessary to subdue their victims. Because of the extensive physical injuries that often accompany these rapes, battering rape victims may seek help from emergency rooms, battered women's shelters, and police (although they rarely reveal the sexual assaults to service providers).

Battering rapes are certainly a widespread and serious problem. However, it is important to heed Russell's warning that wife rape should not be subsumed under the battered women rubric. Marital rape is by no means limited to battered women.

Force-Only Rapes

Force-only rapes occur in marriages that are not otherwise physically violent (or have included only minor violence) where the husband uses only as much force as necessary to coerce his wife into sex. The victims of force-only rapes in the Finkelhor and Yllo study tended to be more highly educated women with professional occupations than the women who experienced battering rapes. The sexual assaults occurred largely in the context of marital conflicts, especially disagreements about sex. Force-only rapes were less frequent throughout the course of the marriages; nevertheless, they were still experienced as painful and frightening attacks.

In force-only rapes, power seems to be the primary motivating factor. Groth describes such rapists as wanting to possess the victim sexually rather than to harm her physically. Sexuality becomes the means to express dominance, control, and mastery. The goal is sexual conquest, and only the amount of force necessary to achieve this end is used. Because victims of force-only rapes are not beaten and have no severe injuries, they are unlikely to come to the attention of medical or criminal authorities and are least likely to find redress in the courts.

Sadistic Rapes

Sadistic (or obsessive) rapes account for only a small portion of all marital rapes; however, they are among the most damaging to their victims. They may involve severe physical violence and torture or intense psychological abuse, but all involve some sexual perversion. The perpetrators

of sadistic rapes are more likely to use objects, involve additional men, stage and script assaults, and most importantly, be sexually aroused by their aggressive and abusive behavior and their wives' suffering. They tend to be obsessed with sex and immersed in pornography, which they often force their wives to reenact.

Groth's research identifies the motivation of sadistic rapists in the erotic fusion of sex and aggression. The assaults often involve ritualistic elements, and the perpetrators are gratified by their victims' torment and suffering. Victims are emotionally traumatized and often deeply ashamed, making it difficult for them to seek the help that they need.

Effects of Marital Rape

Research indicates that marital rape has severe and often long-lasting consequences for women. The physical trauma of the violence and rape include genital and rectal injuries, lacerations, bruises, and broken bones. Miscarriages and unwanted pregnancies are reported by about one fifth of victims. The contraction of HIV/AIDS and other sexually transmitted diseases can also be a consequence of forced sex in marriage.

Russell's representative sample survey found that a greater portion of victims of marital rape report that the assault had a serious effect on their lives than victims of stranger rape. Other research suggests that in addition to the emotional effects, including terror, posttraumatic stress, and anger, marital rape victims are especially traumatized by the violation of trust that the assaults represented. They tended to question their own judgment of men and experience difficulties in subsequent intimate relationships.

One reason that the effects of marital rape can be so devastating is that the crime is largely unreported and victims receive little support from health care providers, therapists, religious advisors, or the criminal justice system. Although there have been improvements in addressing domestic violence and general sexual assault by professionals, marital rape remains a secret trauma for most victims.

RAPE, PRISON

Prison rape is a serious, not uncommon, harmful act that impacts victims, operations of correctional facilities, and society in general. However, both scholars and correctional officials lack full understandings of this topic. Although developments in the first years of the 21st century have highlighted the importance of the issue, prison rape has not always been considered important or worthy of much research and attention. As reported in Richard Tewksbury and Elizabeth Mustaine's study of all corrections-related research articles published between 1990 and 1999, in the five major corrections journals identified, only 0.1% of all articles addressed sexual behavior in correctional facilities and 0.8% of articles focused on any type of victimization of inmates while incarcerated. However, there are important reasons to address prison rape, including to understand institutional culture better, the consequences of sexual violence (including injuries and sexually transmitted diseases), and if and how sexual violence is related to other forms of institutional violence. However, as is demonstrated below, little scholarly attention was focused on this issue. However, it was not only scholars and researchers who devoted such a small amount of attention to

prison rape. So too did corrections officials consider the issue unimportant and a topic that had little bearing on prison and jail operations.

The lack of attention and concern with prison rape, however, changed dramatically in the early 1990s. As more attention, via media reports of victims speaking out and the efforts of the non-profit organization Stop Prisoner Rape, was focused on sexual victimization of incarcerated individuals, public sentiment and governmental action began to change. Concerns about the effects of prison rape on inmate victims and on the overall safety and security of prisons and jails led to the passage of the Prison Rape Elimination Act of 2003 (PREA). This federal legislation was designed to not only bring attention to the issue but also to lead correctional officials to develop zero tolerance policies, identify and implement effective prevention and intervention programs, spur additional research and data collection, and then lead to the development of operational standards for all correctional facilities—including adult prisons and jails, juvenile facilities, military and immigration facilities, and short-term detention facilities such as police lockups. These standards are designed to address issues of prevention, intervention, services for victims, and effective prosecutions of perpetrators.

Definitions of Types of Sexual Violence in Corrections

When discussing prison rape, several types of sexually violent acts are included in the issue. For many observers, the idea that comes to mind is that which has been promoted through popular/entertainment media—violent, often gang, forcible rape of weak inmates by long-term, violent inmates. However, the idea of prison rape includes not only the stereotypical types of events but also the “less serious” instances of coercive (as opposed to forcible) sexual activities, sexual contacts not involving penetration, and sexual misconduct committed by correctional staff.

In an effort to promote and encourage data collection and research products that are directly comparable with one another, the Bureau of Justice Statistics of the U.S. Department of Justice and the federal Centers for Disease Control and Prevention defined three types of sexual violence for guiding such efforts. Each of these definitions as established is listed as follows.

- *Nonconsensual sexual acts* are defined as contact of any inmate without his or her consent, or of an inmate who cannot consent or refuse, and contact between the penis and the vulva or the penis and the anus involving penetration, however slight; or contact between the mouth and the penis, vulva, or anus; or penetration of the anal or genital opening of another person by a hand, finger, or other object.
- *Abusive sexual contacts* are defined as contact of any inmate without his or her consent, or of an inmate who cannot consent or refuse, and as intentional touching, either directly or through the clothing, of the genitalia, anus, groin, breast, inner thigh, or buttocks of an inmate.
- *Staff sexual misconduct* refers to any behavior of a sexual nature directed toward an inmate by an employee, volunteer, official visitor, or agency representative; all completed, attempted, threatened, or requested sexual acts between staff and inmates; any incident of intentional touching of the genitalia, anus, groin, breast, inner thigh, or buttocks with the intent to abuse, arouse, or gratify sexual desire; and incidents of indecent exposure, invasion of privacy for sexual gratification, or staff voyeurism.

Although these definitions guide official data collection and the ways that correctional officials design and implement policies and prevention efforts, it was not until the passage of PREA that such definitions were used. Early research regarding prison rape used a variety of definitions, typically developed by individual researchers. However, this lack of uniformity in definitions was problematic, as different researchers measured different things. Consequently, the research on prison rape completed prior to 2003 often reached widely ranging conclusions about how common such actions were. This lack of consistent operationalization of the issue has been identified by Gerry Gaes and Andrew Goldberg as a major problem with the early research on prison rape.

Rates of Victimization

Attempts to answer the question of how often prison rape occurs have produced widely varying responses, with rates running from zero to more than 20% of all inmates. Generally speaking, data

that come from official sources (e.g., documented reports that victims make to correctional officials) and that which uses the broadest definitions (e.g., “had sex with another inmate when you did not want to”) has shown the highest rates of victimization. Most data collected from inmates’ self-reports, and that which uses more narrow definitions (e.g., “were physically forced to engage in intercourse”), tend to show lower rates of victimization.

The first valid and reliable estimation was from Alan Davis’s 1968 study of the Philadelphia jails. This study, drawing on interviews with more than 3,300 inmates, 570 staff, and reviews of institutional records, documented 156 incidents of rape; however, Davis also estimated that the true number of incidents for the more than 60,000 inmates to pass through the system during the 26-month study period was closer to 2,000. Two decades later, Tewksbury’s 1989 study in one Ohio prison, however, reported an absence of self-reported sexual violence. Saum and colleagues’ 1995 study of 101 Delaware inmates revealed only one completed rape and five inmates who reported that another inmate had attempted to rape them. In 1996, A. S. Maitland and R. D. Sluder reported that in one Midwestern, medium-security prison, only 0.9% of surveyed inmates reported having been sexually victimized while incarcerated.

A series of studies in the 1990s and early 2000s by Cindy and David Struckman-Johnson reported significantly higher levels of victimization. Fully 22% of inmates in one study reported being a victim of sexual coercion. And in a study of seven Midwestern prisons, anonymous surveys by inmates revealed that 21% of male inmates reported at least one instance of forced or pressured sexual contact. This study also showed that 20% of inmates reported sexual coercion or assault perpetrated by a staff member.

However, others studying the issue prior to the implementation of PREA reported that only 1% of Oklahoma inmates reported an instance of sexual victimization. Additionally, a 2005 study in Kentucky reported a victimization rate of 8.5%.

Research Inspired by the Prison Rape Elimination Act

After the passage of PREA in 2003, numerous studies of prison rape have been completed.

Included among these efforts are several studies of statewide correctional systems and a major federal effort to identify a national estimate of the rate of victimization.

Studying the Texas prison system, James Austin and colleagues reviewed more than 3 years of data and showed that 2% of the inmates were either a victim or a perpetrator of prison rape. During the course of 3 years and 8 months, a total of 1,938 instances of prison rape were reported by inmates; however, according to Texas officials, only 43 (2.2%) of the allegations were sustained after investigation. In a study of one mid-Atlantic state’s prison system, Nancy Wolff and her colleagues report that 1.4% of male inmates and no female inmates reported nonconsensual sexual activity in the previous year. In contrast, however, Struckman-Johnson and Struckman-Johnson’s 2006 surveys of 1,788 inmates in 10 Midwestern prisons revealed that 21% of males and 19% of females report victimization.

One of the important provisions of PREA was that the federal Bureau of Justice Statistics was charged with the task of conducting a national study to estimate the rate of prison rape in all varieties of federal, state, and local correctional facilities. The first two products of their efforts reported on the number and rate of instances officially reported to correctional authorities. Data from 2004 show that more than 8,200 incidents were reported in adult and juvenile correctional facilities. Of these reports, one quarter were substantiated by investigations. Rates were highest in both state-operated and private juvenile facilities and lowest in state prisons. Of all allegations reported by correctional authorities, 41% involved staff-on-inmate sexual misconduct, 37% inmate-on-inmate nonconsensual sexual acts, 10% inmate-on-inmate abusive sexual contacts, and 11% were staff sexual harassment of inmates. In 2005, 6,241 allegations were reported in adult facilities (the 2005 report does not include data from juvenile facilities). The 2005 rate represents a slight increase in the rate of allegations per inmate from 2004 (2.8/1,000 in 2005 compared with 2.5/1,000 in 2004). As in the previous year, the most common reports were of staff-on-inmate incidents (38%).

The most recent, and most methodologically sophisticated, study of the rate of prison rape was released in 2007. This study, conducted by the Bureau of Justice Statistics, draws on anonymous,

computer-administered surveys with a sample of 23,398 inmates from 146 prisons in all 50 states. Results show that during the previous 12 months, 4.5% of all federal and state inmates report a sexual victimization by either a correctional staff member or another inmate. Inmates are more likely to be victimized by staff (2.9% of all inmates) than other inmates (2.1%). Of the 146 facilities where data were collected, only 6 had no inmates report victimization in the previous year.

Conclusion

Clearly, prison rape is an important issue and something that has wide-ranging effects. Although some critics may claim that “only” about 4% of inmates are victimized, when we think about the fact that on any given day more than 2.2 million adults are in our nation’s prisons and jails, we are talking about a significant number of persons. Add to this the fact that little is known about the long-term effects of prison rape on recidivism, health, institutional adjustment/behavior, and a range of other possible consequences, and it is obvious that the issue of prison rape is a major concern in the field of criminal justice and victimology.

RAPE, PROTECTION AGAINST

An important aspect of prevention of rape is a woman’s ability to protect herself from attack. Because effective primary prevention of sexual aggression is still lacking, women, who are the most frequent targets of rape, need education about effective resistance strategies if confronted with an assault. Such an approach does not imply that women are responsible for stopping sexual assault and is actually ethically warranted to help women to respond to an assault until we can prevent men from committing assaults. Active resistance strategies can help women to avoid rape, but psychological barriers to resistance must also be addressed to enhance avoidance of acquaintance rape. Research documenting women’s ability to resist and avoid completed rape can help to inform effective risk reduction focused on resistance and self-defense training. More research is needed to address close relationship contexts (e.g., partner/spouse), history of child sexual abuse, and alcohol-involved assaults that can interfere with a woman’s ability to identify and engage in effective resistance to assaults.

Situational and Behavioral Risk Factors

Research shows that risky situations like bars, parties, and isolated areas increase risk of sexual assault. Alcohol use and violent partners also confer added risk of adult sexual assault for women, as does a history of child sexual abuse. Women’s resistance seems to be effective regardless of rapist type, but little research exists on this subject. Multiple assailants, weapons, indoor attacks, attacks at night, attacks by multiple assailants, attacks without bystanders, and those by intimates are more likely to result in rape completion, perhaps partially because of less resistance or use of less effective resistance. Although most research on rape risk and resistance focuses on stranger and acquaintance sexual assault, sexual assault also occurs in the context of relationships, which is much more difficult to avoid. Still, forceful

resistance, although much less likely in assaults with alcohol involved or in intimate relationship contexts, can be effective if used. It seems that weapons are related to greater odds of completed rape, partly because resistance is less likely in these assaults. Less resistance to known perpetrators seems to be caused by psychological barriers, including fear of angering the man and feelings of embarrassment. In addition, among women who are drinking (which is especially common in college sexual assaults), they may feel responsible for and/or blameworthy for putting themselves at risk, because of society's negative attitudes about drinking women. As a result, they may decide not to resist in such assault situations and/or if they are impaired may be unable to do so.

Effects of Victim Resistance Strategies

Research has shown that offender force and violence is the strongest predictor of the level of victim injury. Victims are more likely to resist physically in such cases and to avoid completed rape. Studies of both college and community samples have shown that women who resist with forceful physical and verbal resistance are more likely to avoid rape and physical injury, whereas nonforceful verbal resistance or not resisting is ineffective. Most important, it does not seem that active forms of resistance such as fighting back increase risk of injury. Data from the National Crime Victimization Survey shows that the efficacy of active forms of resistance seems to hold up even when controls for situational context factors are included. Despite this, research is needed on subgroups of women who may have more difficulty resisting an assailant, such as women who are heavy drinkers, those who have histories of child sexual abuse, and those in ongoing violent dating or marital relationships. Engaging in effective resistance may require unique specialized training approaches for women in some of these circumstances, and risk reduction program must be tailored to address various types of assault circumstances.

Translating Knowledge About Resistance Into Risk Reduction

Traditional rape prevention strategies with women have been focused on risk reduction involving

teaching women facts about rape, information about risk factors, and how to avoid them, but not about risky contexts and situations and effective resistance, including actual resistance/self-defense training. Recent experimental research with college women has shown that teaching self-defense training and addressing psychological barriers to resistance (e.g., fear of angering the man or being embarrassed) can lead to less rape at a later follow-up. In addition, self-defense seems to help women to be more assertive in their sexual communication, engage in more self-protective behaviors, and feel more efficacious about resisting sexual assaults. It seems that teaching women self-defense and working to reduce psychological barriers that hinder resistance to attacks may help women avoid future rapes. More in-depth specialized prevention programs may be needed for child sexual abuse survivors and for women in violent relationships. More attention is needed not only to evaluate resistance/self-defense training interventions, which seem to be promising, but also to evaluate their applicability to various subgroups of victims and assault situations. Translating existing knowledge about effective resistance into education and training for women and girls is important because reducing completed rapes can help to reduce its consequences, which include depression, anxiety, and other psychological and physical health consequences of completed attacks.

RAPE, THEORIES OF

Scientists agree that evidence of rape in society dates back as far as the human race, although archeologists have discovered some human societies for which no evidence of rape can be found. Scientists have also revealed instances of “rape” within many nonhuman species. However, the phenomenon of violence and sexuality in humans has long puzzled scientists and raises serious concerns for many feminist, social, and legal theorists. At the root of this perplexity is the apparent inability to define rape. This entry examines four theories that during the years have been formulated to examine, explain, and respond to rape: the feminist theory, social learning theory, evolutionary theory, and synthesized theory. These theories examine rape from both the perspective of the victim and that of the perpetrator. Often the disparity between the theories depends heavily on the definition of “rape” or “sexual aggression” relied on by the scientists.

Defining Rape

Historically, legal documents dating as far back as 1780 B.C.E., such as the Babylonian law Code of Hammurabi, stipulated virgins were innocent of rape, whereas married women were considered guilty of adultery when raped and could be executed. Remnants of this law still exist in the United States. Some courts refuse to recognize rape between married individuals, whereas other courts have required evidence that the marriage was terminated prior to the incident in order to constitute rape.

The ability to provide clear and concrete definitions of rape is thwarted by the vast differences in the way both males and females view sexual relationships. The Uniform Crime Reporting (UCR) Program, disseminated by the Federal Bureau of Investigation and compiled from reports made to law enforcement agencies, codifies and classifies instances of rape. The UCR Program examines primarily the female victim, thus, defining rape as a male-perpetrated crime. Studies, however, have increasingly shown that men are victims of rape and that women are perpetrators as well. The UCR Program also excludes statutory rape (in which rape is defined by the disparity in age between the perpetrator and the victim). Often, in these types of cases, the sexual encounter was consensual and, thus, generally should not be considered “rape.” In recent years, reports that identify rape have begun to include male victims, female perpetrators, studies of rape in prisons, marital rape, date rape, along with violent rape; however, vast disparities between what theorists believe constitutes rape still exist.

The legal definition of rape differs from assault in that “lack of consent” is an element of the crime. Victims are required to show that the sexual assault was unwanted and refused. To what degree a victim must refuse or resist is highly disputed among legal, medical, and social scientists. The efforts to codify instances of rape are an attempt at addressing this issue.

The use of force during sexual encounters generally is required to constitute rape. This definition includes instances of rape in prison, serial rapists, rape used as a war tool, and violent stranger rape. Historically, violent rape has always been proscribed with a few exceptions such as for married females or prostitutes. Many of today's social scientists would

like to see a broader definition used to define rape. Some rape theorists argue that “the use of force without consent” requirement rarely is adequate to take into account instances of acquaintance, marital, or statutory rape. Although theorists do not agree on what constitutes rape in all circumstances, they have formulated theories to address possible causes, treatment, and prevention of sexual violence.

Feminist Theory

One of the first and leading feminist theorists on rape, Susan Brownmiller, contends rape is a form of intimidation consciously used by men to keep women in fear. Other rape theorists argue this is too broad because it implicates all men. However, it is too narrow to encompass all of the purposed types of rape. Primarily, feminist theorists believe that the economic and political gender discriminatory policies promote and facilitate instances of sexual and other violence against women. The historical definitions of rape or *rapere*, which is Latin for stealing, have addressed rape as a property crime, whereby the rapist had not violated the female per se but those who were financially responsible for her, either father or spouse. The use of women as chattel reduced women to mere objects, and the equalization of women in society would eliminate sexual violence against women. In support of this theory, studies of cultures where women were in prominent social, political, and economical positions found low rates, if not the absence, of rape.

The perpetrator according to this theory of rape is not committing a sexual act but instead an act of violence. Here the rapist wishes to possess, dominate, and demean his victim. Some feminist theorists contend the act is motivated by desires of power and hatred for women, not sexual urges. Often it is here that feminists disagree. The more widely accepted feminist view centers around the equalization of social and economic power between men and women as a preventive measure to rape. Studies have shown that poor and less educated women are more likely to be sexually attacked than wealthier educated women. In addition, studies have indicated that often the rapist is of a lower income status and less educated than the victim. Some feminists argue that although increasing the level of income and education for women may

reduce their likelihood of being attacked as compared with lower income women, it may threaten the status of men and intensify their use of rape to reassert their loss of supremacy.

According to studies from the early 1980s, most victims know their aggressor. The feminist theory examines the traditional sex role stereotyping when deciphering the victim. Feminists concluded that women who displayed passive or sacrificing behaviors were more likely to be victims than those with more aggressive personalities. In studies of college students, 30% to 50% of the dating relationships were found to be violent courtships. The higher rates were among the lower income. Again the vast difference in the way appropriate courtship is viewed among women hinders the ability to identify, prevent, and treat rape victims. Factors such as age, education, income, and access to political power have been shown to influence greatly the likelihood of being a victim.

The feminist theory, though, does not explain why men rape men or why females are perpetrators of rape. It is here that some theorists turn to the social learning theory to explain such phenomena.

Social Learning Theory

The social learning theory examines the impact on an individual of continued exposure to rape and other violence against women. Social learning theorists assert that violence such as rape is learned. Proponents of this theory much like feminists contend that the existence of rape in our society stems from the exposure to sexual violence and not to extracultural or nonlearning variables such as genetics. The rapist is created by his environment. These theorists maintain that continued exposure to a stimulus naturally creates positive feelings toward it. Often persons with phobias are treated with methods that involve exposing the person little by little to the phobia and eventually the person can grow accustomed to it if not completely overcome their fear.

The social learning theory codifies the effect of continued exposure to sexual violence into four categories: *modeling effect*, *sex-violence linkage effect*, *rape myth effect*, and *desensitization effect*. The modeling and sex-violence linkage effects contend that individuals exposed in this fashion to rape, pornography, domestic violence, sexual

assault, and other forms of violence are more likely to exhibit sexual aggression and violence. In particular, the modeling effect contends that where an individual is actually taught as opposed to simply being exposed to violence, he or she is at a higher risk for committing violence. The rape myth effect examines social portrayals of females enjoying rape, and the desensitization effect argues that the continued exposure to certain forms and images of sexual violence in horror movies, urban music, Internet, and other forms of media normalize rape.

Unlike some feminists, social learning theorists contend that rape can be precipitated by a sexual desire as opposed to hatred or power. These scientists argue that the effect of continued exposure to sexual violence confuses the aggressor, and in certain cases, he no longer differentiates between rape and sex. Although social learning theorists would agree with many of the feminist contentions that the gender disparity in economics and political power perpetuate the continued usage of these images, they would disagree that the rapist rapes merely to conquer. The social learning theory can encompass sexually violent crimes where the victim is male or whereby the perpetrator is female. The contention that we learn violence, and thus become violent, explains more types of sexual violence schemes than does the feminist theory; however, it is not all encompassing. Moderate social theorists often team with psychologists and other medical scientists to examine the biological effects as well to help explain sexual violence.

Today, theories used to govern the treatment and rehabilitation of sexual offenders profess the necessity of examining both cultural and biological factors. Modern social rape scientists continually examine images in media, antisociality, and self-reports of exposure to violence. However, this theory does little to help scientists understand why there is evidence of rape in nonhuman species and why many who are taught, highly exposed, and abused are not violent, nor does it adequately address the data that indicate some rapists show no evidence of having "learned" how to rape. The evolutionary theory attempts to answer these remaining questions.

Evolutionary Theory

Evolutionary rape theorists examine the evolution of the human species and how it effects and relates

to the commission of violence against women, including rape. Initially the evolutionary rape theory attributed the propensity to rape to mental illnesses or deficiencies. Historically, these theorists saw rape as a rare occurrence only contributed to the deranged or to careless victims. These theorists contended that the rapist was an anomaly to the evolution of the human species. The need to procreate and the need to adapt to further survival are interpreted to be at the root of sexual aggression in these males. The interpretation of rape as a by-product of a procreative agenda lent credence to phrases such as "Boys will be boys" when explaining sexual aggression.

In 1893, renowned evolutionist, Charles Darwin, was vehemently contested by feminists such as Antoinette Brown Blackwell and Eliza Gamble. Blackwell insisted that the evolutionary evidence indicated equality between the sexes, as opposed to Darwin's claim of male dominance. Gamble went so far as to assert that the science established the female sex was superior. In the new millennium, evolutionary science has made a comeback, greatly modified. Scientists contend the evolutionary theory has unjustly been given a bad reputation for being sexist. Modern evolutionary scientists insist that their rigorous scientific methods of research lend not only clarity to the issue of violence against women but also to many social phenomena.

Today's scientists who use evolutionary evidence do so simply to provide a more individualistic analysis as opposed to the often generalized social perspective. Foundationally, these scientists examine the sexual rituals of animals, for example, the male lions in the African Savannah to explain sexuality in humans. The male lions often exhibited sexual aggression. When a senior male lion was challenged for his place in the pride and lost, all of his cubs were systematically killed and his lionesses became mates for the victor. Thus, these scientists contend that sexual conflict between the sexes is inherited. In 2000, evolutionists affirmed that rape can be contributed to evolutionary methods of human male mating strategy. The male's need to reproduce requires him to develop methods by which to accomplish the instinctive prerequisite. They conclude that those males who for whatever reason are procreate challenged resort to rape or sexual violence as a by-product of an evolutionary need to survive.

In 2003, scientists contested this theory, pointing to the failure to consider the female's role in reproduction. Scientists argue that some evolutionists have failed to interpret the evolutionary science objectively. This is pronounced by their exclusion of evidence in their theories of instances such as the hermaphroditic sexual reality in the hyena species. The female and male genitalia of the hyena are analogous. The female thus responds sexually much like "males" and can be found to mount as well as exhibit aggressive behavior toward the males. This sexual aggression was not deemed as a need for procreation. In addition, rape is significantly committed by men who seem to have no difficulty in procreating, who intentionally refuse to copulate with victims, and by individuals who claim no sexual arousal from the act. They contend that these scientific examples of sexual aggression for nonprocreative motives contravert the evolutionist theory.

Often references to natural selection, fitness, and environment are made when formulating conclusions to support the assertion that one has predisposed factors that contribute to sexually violent behavior, namely a need to procreate. The question of whether sex in the animal kingdom is fundamentally about reproduction is questioned by evolutionists, and the study of sexual behavior is continually providing evidence to the contrary. Scientists emphasize that where forced copulation occurs, it is rarely an effective means of reproduction. Furthermore, the assertion that sexual violence is a product of adaptive reproductive mechanisms is well contested. Evolutionists contend that those who are environmentally, socially, or biologically unfit for reproduction instinctively to further their need for survival, thus using mechanisms of rape for that end. However, other scientists contend that the necessary evidence is paucity to show that rape is a successful method of reproduction if it exists at all.

The evolutionary theory unfortunately attributes sexual behavior to procreation. This apparent flaw in the fundamental analysis of sexuality renders much of the practical conclusions ineffective in the prevention or treatment of rape. This theory purportedly contributes to solutions such as warning women about wearing seductive apparel, the innately predatory nature of men, and raising the level of aggression in women. Social learning scientists argue the above methods have not been

shown to influence the rate of rapes nor the identity of the victim in significant ways.

Synthesized Theory

The synthesized theory of rape attempts to combine useful evidence from all three aforementioned theories of rape to better understand the phenomenon while including biological elements such as hormonal implications. The synthesized theorists conclude that the feminist theory is correct in that the drive to possess and control is an underlying cause of rape; however, synthesized theorists also contend that the sex drive of the individual also plays a significant role. Second, the actual technique of rape is learned; however, not all men are of a nature to learn how to rape. Third, evolution has naturally selected men as opposed to women to use force to reproduce. Last, exposure of the brain to high levels of male typical sex hormones increases rape tendencies.

The criticisms of the feminist, social learning, and evolutionary theories discussed prior can be lodged against the synthesized theory here as well. The synthesized theory also raises an additional issue of hormones and their effects on the commission of rape. Unlike the other theories, this theory examines the functioning and mechanisms in the brain to determine how rape is learned and motivated. These scientists contend that all influences must operate via the brain whether environmental or genetic. They argue that the brain of the rapist while committing the offense functions very differently from that of others. This theory must be more stringently tested. Currently, the evidence is not conclusive.

Current Status

Scientists continue to struggle with defining rape and thus with formulating theories to identify its causes. As this entry has shown, four factors significantly play a role in the cause of sexual assault: economic and political inequality between the genders, environmental factors, genetics, and lastly biochemistry. Although great debate continues as to which of the factors plays the greater role in the cause of rape, the collaborative quest to end this tragic social phenomenon continues.

RAPE, VICTIM-PRECIPITATED

Victim precipitation is a concept used to define situations in which the victim initiates his or her own victimization. When applied to rape, victim-precipitated rape occurs when the victim's actions are interpreted by the offender as sexual, thus initiating subsequent behavior (e.g., forcible rape) from the offender. The examination of victim-precipitated rape is not without controversy. Controversy erupts regarding whether applying the concept of victim precipitation to rape is a veiled attempt at blaming the victim for his or her own victimization. Additionally, studies that have explored victim-precipitated rape have been criticized for relying on poor methodology.

Development of Victim Precipitation

Marvin Wolfgang first introduced the concept of victim precipitation when he argued that, in some instances, the victim may provoke his or her own victimization. Wolfgang defined a homicide as victim precipitated when the victim was the first to use physical force. To test his assertion, Wolfgang collected official data on 588 homicides committed in Philadelphia from 1948 to 1952. Wolfgang found that about one in every four murders in Philadelphia were victim precipitated. Subsequent studies have expanded on the work of Wolfgang to look at other factors of victim precipitation, such as self-defense issues, intimate partner homicide, and rape.

Application of Victim Precipitation to the Study of Rape

Theoretically, victim precipitation of forcible rape involves a situation where the behavior of the victim is interpreted by the offender as a direct invitation to sexual relations. What becomes important is the offender's interpretation of the victim's behavior in the current situation. Certain behavioral patterns (e.g., being flirtatious, provocative, or sexually aggressive) and certain situations (e.g., partying at bars late at night or deliberately walking in dark alleys after dark) may suggest to the offender that the victim wants to engage in sexual relations, when in fact they do not, leading to the sexual assault of the victim.

Menachem Amir, a student of Wolfgang's, was the first to apply the concept of victim precipitation to rape. Amir defined victim-precipitated rape as situations in which the victim agreed to sexual relations but retracted before the actual act or did not resist strongly enough to the offender's sexual advances. Like Wolfgang, Amir used official data on rape collected in Philadelphia from 1958 to 1960. Examining 646 cases of forcible rape, Amir found that 122 cases, or 19%, fit his definition of victim precipitation. His findings also showed that most victim-precipitated rape cases involved White victims with a White offender, young (15 to 19 years of age) victims, alcohol use (particularly by the victim), and involved bars as a common meeting place.

Criticisms and Clarifications

Amir's research on victim-precipitated rape was not well received and subject to much criticism. Most criticism revolves around Amir's conceptualization of victim precipitation and his focus on the offender's interpretations of the victim's actions. Additionally, Amir's work was criticized for not only including a definition of precipitation that is broad and unclear but also for proposing instances where the victim was guilty of precipitating her own sexual assault because either the offender interpreted her actions as a "green light" to go ahead and/or she did not forcefully fend off the offender's sexual advances. Feminist scholars were particularly disturbed and argued that Amir used rape myths to justify sexual assault and blame the victim for her own victimization.

Because of such criticisms, it becomes important to distinguish between victim precipitation and provocation. Provocation is a legal concept used to determine the criminal responsibility of the accused. Victim precipitation is a behavioral concept used by social scientists to determine the causes of victimization. Provocation relies on the behavior of the offender (specifically his or her mindset and the level of restraint), whereas victim precipitation relies on the analysis of the victim's behavior at the time of the victimization.

Victim-Blaming and Victim-Defending Views

Victim precipitation is often regarded as a form of victim blaming. The victim-blaming perspective, when applied to rape, contends that the victim contributes to his or her own rape because of his or her actions. For instance, victims may not understand or may ignore certain situations that put them at risk of victimization, such as being out late at night unescorted, wearing provocative clothing, or being intoxicated. A consequence of accepting the victim-blaming viewpoint is that the burden of preventing rape is shifted away from the offender, the police, or the popular culture, and onto the victim herself.

Victim-defending questions the concept of precipitation. Originally developed by feminists in the women's rights movement, victim defending provides alternative explanations for why victims get raped. From a victim-defending perspective, it is

unacceptable to suggest that the victim's behavior justifies the actions of the offender. Rather, the blame is placed on the assailant's intentions to control, overpower, and humiliate the victim. The offender's violence is not triggered by arousal but is motivated by contempt for females. Victim-defending questions the concept of precipitation, as there is no such thing as a justifiable rape.

Controversy remains in determining what constitutes sexual overture. A victim's behavior can be open to a wide range of interpretations, including those of the victim, the offender, the police, a jury, the public, and researchers. Despite the limitations inherent with victim precipitation research, the concept of victim precipitation allows for the consideration of situational factors into the equation, providing a richer, more thorough explanation of rape.

RAPE AND CONSENT ISSUES

At the core of the controversy surrounding rape is the concept of consent to sexual activity. Consent is particularly at issue when the people involved in a rape have a prior relationship with each other. These relationships include spouses, dating partners, boyfriends and girlfriends, friends, and acquaintances. Because most rapes involve people who know each other, defining consent is a crucial

component to the prevention of this common crime. This entry defines consent, discusses the legality of consent in sexual encounters, and describes efforts to prevent rape through providing education about rape and consent to youth.

Addressing the issue of consent has been a major component of the anti-rape movement, particularly with regard to those rapes involving people who know each other. Because these cases frequently involve one person's word against another person's word, consent becomes an important consideration, especially when criminal charges are filed. That the sexual activity was nonconsensual is a general statutory requirement for a rape to have legally occurred. In addition, suspects accused of raping people they know frequently use the "consent defense," asserting that the person they are accused of raping consented to the sexual activity. Rapists sometimes use the "consent defense" to intimidate victims to not report the crime. For example, a rapist may threaten a victim with telling people that the sexual activity between them was consensual. Some rapists take this one step further and tell the police and others that the victim initiated the sexual activity leading up to the rape in an effort to deflect blame from themselves and onto the victim. It is sometimes the case that people who initiate sexual activity are raped. When the activity goes beyond what the initiating party believes is acceptable and what he or she has consented to, the encounter is no longer consensual and becomes illegal.

Defining Consent

When a person consents to sexual activity, this means that he or she knowingly and willingly participates in the activity. The terms *knowingly* and *willingly* require that a person is aware of the decisions being made and is aware of the potential consequences of that decision. This means that for sexual activity to be consensual, one person cannot trick, coerce, or force another person into the activity. Trickery, coercion, and force can occur in many ways, including verbal intimidation, physical force, threatening to spread rumors, and getting someone drunk or high for the purpose of having sex. All of these actions violate the requirements of knowledge and willingness by removing a person's capacity to make the decision to participate or by not making refusal to participate an option.

Consent is often confused with the terms *compliance* and *submission*. Compliance means doing something even if a person does not agree with the action. For example, people comply with work policies even if they do not agree with them because there are likely consequences for violating the policy. Rape victims comply with a rapist's demands to prevent negative consequences such as physical injury. Submission means not having the power to stop an event from happening. An example of submission is a recruit at military boot camp training. The recruit must submit to the will of the drill instructors because he or she is powerless to refuse. Similarly, a rape victim's submission to a rapist's demands occurs when the victim is powerless to stop the rape. Sometimes a rape victim has to both comply and submit to what the rapist wants.

Frequently, rape victims who comply with or submit to the demands of their rapist are accused of having consented to the activity. This belief stems from society's expectations of how a person should respond while being raped. Society tends to believe that a person who is being raped should fight back with the utmost verbal and physical resistance in order to avoid an attack or at the very least to prove that the sexual activity was unwanted. A tendency exists for people to believe that if resistance does not occur, the event was not a rape. Several things must be considered regarding this societal expectation. First, it may not be possible for a victim to resist an attack verbally or physically. Victims who are under the influence of drugs or alcohol, whether they willingly or unwillingly used these substances, are unlikely to resist because of the impact of drugs and alcohol on a person's mental and physical capabilities. Nor can people under the influence of alcohol or drugs legally consent to sexual activity. Some rapists intentionally drug their victims or get them drunk so that both physical force and physical resistance are minimal, and so that the victims will not have a clear memory of the rape. Second, many people are frightened and are unable to react in accordance with society's views. Fear sometimes has a paralyzing effect on people. In addition, people are caught off guard when they are raped, which can decrease the likelihood of being able to resist. Finally, the issue of resistance is sometimes considered by prosecutors in determining which cases should be pursued,

and frequently it is discussed at rape trials. Although case law generally states that physical and verbal resistance on behalf of the victim are not a requirement for prosecutors to charge a person with rape, many cases are not charged if resistance did not occur. This is because the likelihood of a conviction at trial is unlikely—juries prefer to see physical evidence that a crime has occurred, particularly when that crime is rape. Victim resistance may result in injuries to either the victim or the rapist, offering juries the evidence they desire.

Much debate exists about what actions constitute consent to sexual activity. Ideally, consent only occurs when a person explicitly and verbally agrees to participate in sexual activity; physical actions are sometimes difficult to interpret and should not be construed as active consent. In the real world, however, this “consent ideal” can be problematic because movement along the continuum of sexual activity is not always clear-cut and multiple actions occur at the same time. In addition, the ideal of consent assumes that people are comfortable voicing their thoughts and feelings. Therefore, a person’s silence when engaged in a sexual activity should not be construed as consent because a person may remain silent out of fear or discomfort.

The issue of revoking consent after it has been given has been controversial. In the late 1990s and early 2000s, courts began widening the definition of rape by ruling that a person can revoke consent to sexual intercourse after that consent has already been given. Speaking strictly in terms of a male suspect and a female victim, critics of these rulings argue that there is little guidance regarding how soon a man must stop penetration of a woman before the act becomes rape. A related issue is that of continued consent within a sexual relationship. Some people believe that when a person consents to sexual activity one time, he or she has therefore consented to sexual activity with their partner at all other times. This belief is frequently used as a means to justify marital rape and rape within other intimate relationships. In addition, sometimes people believe that because a person has sex with someone, that person has consented to have sex with anyone. This belief is particularly popular among high-school students and can lead to detrimental developments in a young person’s life if he or she is the target of this belief.

Legal Age of Consent

Each state has passed a law to determine the age at which a person can legally consent to sexual activity. Although these laws vary, most fall between ages 14 and 18 years. These laws are designed to protect young people from being coerced or forced into having sex before they are mature enough to make an informed decision. Some of these laws have come under scrutiny because teenagers close in age can be prosecuted for having sex. If convicted, the person accused becomes a registered sex offender, which impacts the rest of his or her life. Boys are more frequently prosecuted for these offenses than are girls. As a result of the dire ramifications of a conviction on such a charge, some states are modifying their laws. These “Romeo and Juliet” laws are designed to keep teenagers from having to register as felony sex offenders because they have had consensual sex with their boyfriend or girlfriend. These laws do not change the age of consent, but they allow consensual sex between boyfriends and girlfriends of a certain age difference.

Preventing Rape Through Consent Policies and Education

In the 1980s and 1990s, the issue of date and acquaintance rape on campuses moved some colleges and universities to develop policies that explicitly define consent to sexual activity. In 1998, Antioch College instituted such a policy, which required that students ask permission for all sexual activity at each point in the intimate encounter. Other colleges and universities instituted similar policies, drawing criticism for their actions. Some critics contend that these policies are cases of “feminism gone too far,” and that they only serve to disempower both people involved in the sexual encounter. Other critics contend that these policies place too much of a burden on potential victims to stop a rape from occurring. Little evidence exists regarding the effectiveness of these policies in reducing date and acquaintance rape.

Rape prevention programs for youth frequently address the issue of open communication between dating partners. This education is designed to encourage people to be clear about their sexual boundaries, and much of it is based on the predication that communication difficulties between men

and women are, in part, rooted in sexual norms and stereotypes. From a very young age, boys and girls are taught to act in ways that are thought to be appropriate for their sex. Girls tend to be taught to be tactful and polite in voicing opinions and are encouraged to avoid conflict. Boys tend to be taught to speak their minds openly, be persistent in getting what they want, and not back down from conflict. Rape prevention education encourages both boys and girls to be very clear about their sexual boundaries and to be unafraid to vocalize their wishes. Young people are also taught to be respectful of each other's wishes regarding sexual activity, and that if any doubt exists as to whether the activity is mutually acceptable, they should stop the activity. Another focus of this education is instilling the belief that engaging in one activity on the sexual continuum does not necessarily lead to another activity on the continuum. For example, just because two people kiss, does not mean they have to have sexual intercourse. The goal of these primary education efforts is to change the mindset of young people so that they will educate their friends and their families in the same manner, creating a cultural shift in beliefs about consensual and nonconsensual sex.

The issue of consent in sexual intercourse is at the forefront of the controversy surrounding date and acquaintance rape. The anti-rape movement has made it a focus area, and primary prevention efforts attempt to address consent through educating young people. Consent is a key element to the legal aspect of rape—nonconsent is a necessary component to charging a person with rape. More research on this issue is necessary for the field of crime prevention and victimology to make continued progress in this area.

RAPE AND SEXUAL VICTIMIZATION, MEASUREMENT OF

Measurement of crime in general is a difficult and highly criticized task. Measurement of rape and sexual victimization, which are deeply personal offenses, is all the more complex. Sexual victimization incidents are most often perpetrated by someone the victim knows with one or more of the parties using alcohol, drugs, or both. Inaccurate stereotypes about rape and women lead to confusion as to whether the act was a crime. Women are also concerned about what will happen if they disclose incidents. Despite these difficulties associated with the measurement, it is still important to attempt to acquire an accurate picture of rape and sexual victimizations to be more knowledgeable about how to prevent such incidents.

General agreement exists among many scholars that all measures of sexual offenses in the United States underestimate the true extent of the crime. Different measures are considered to have varying degrees of underestimation. Measurement is tied to the definition of rape and sexual victimization—the broader the definition, the greater the extent of victimization.

Multiple attempts have been made at measuring rape and sexual victimization. These attempts include government data collections, private national surveys, and multiple local/regional measures. The following discusses the most common measures of rape and sexual victimization in the United States. Included in this discussion is a brief description of the methodology of each measure, the strengths and weaknesses of the measures, as well as the results in comparison with other measures.

Types of Measurement

Government Data

The main sources of the extent of criminal victimization in the nation are those administered by the U.S. Department of Justice. These sources

include the Uniform Crime Reporting (UCR) Program and the National Crime Victimization Survey (NCVS). These data series collect crime data by two very different methods. Scholars claim that these data sources substantially underestimate the true incident of rape and sexual assault.

Uniform Crime Reporting Program/ National Incident-Based Reporting System

The UCR Program began in 1929 and is administered by the Federal Bureau of Investigation (FBI). The UCR Program is based on crimes reported to state and local law enforcement agencies and in turn reported to the FBI. The UCR Program collects sexual victimization data on the offense of rape with women as the victim. In an effort to extract more specific information about crime, the FBI intends to replace the UCR Program eventually with the National Incident-Based Reporting System (NIBRS). The NIBRS is incident based and includes four categories of sex offenses: forcible rape, forcible sodomy, sexual assault with an object, and forcible fondling. Unlike the UCR Program, male victims are included as forcible rape victims in the NIBRS data. Not all states have been certified to report NIBRS data. Therefore, the only national data the FBI reports are based on the UCR Program definition.

Several limitations exist to the UCR Program's measurement of sexual offenses. The major limitation of the UCR Program is that it excludes victimizations not reported to police, and victimization research has shown that most sexual offenses go unreported. Most rapes are acquaintance rapes, which are much less likely to be reported to the police. Additionally, the UCR Program narrowly defines rape as sex taken forcibly against a female's will. It excludes male victimization and a wide range of other sexual offenses. Another limitation is that reported numbers of sexual assault may reflect general organization factors about police departments and specific ways in which they manage rape victimizations.

National Crime Victims Survey

The National Crime Survey (NCS), now the National Crime Victims Survey (NCVS), began collecting data in 1972 and is under the auspices of the Bureau of Justice Statistics. The NCVS is based

on a household survey of individuals' experiences with crime victimization and on whether the incidents were reported to the police. The survey provides a detailed picture of crime incidents, victims, and trends from the victims' perspectives.

The NCVS is the nation's second largest ongoing household survey. It collects victimization data from a nationally representative sample of individuals age 12 years or older living in U.S. households. Sample respondents are interviewed every 6 months for a total of seven interviews during a 3.5-year period. The first and fifth interviews are face-to-face, whereas the rest are by telephone, when possible.

The NCVS process of collecting victimization data includes a two-step process. Respondents are first asked to respond to a series of "screen questions" on whether victimization may have occurred. These questions are intended to cue the respondent to remember victimization events. When respondents indicate yes to any of the screen questions, they will be interviewed through a lengthy "incident report" about what may have occurred. The NCVS uses the incident report to determine, and thus count, whether victimization has occurred. The use of the incident-report questions validates the occurrence and allows for more valid categorization of incidents.

The major strength of the NCVS versus the UCR Program is that it collects victimizations that go unreported to the police. The NCVS is also based on a large national sample that allows for comparing rates of sexual victimization across a time period and with other forms of criminal victimization within a clearly bound reference period. Another key strength of the NCVS is the use of screen questions and incident reports, which allows for the assessment of rates, verification of the crime, and a more clear understanding of the issues surrounding the offense.

One limitation of the NCVS as a measure of sexual victimizations is that sexual assault is a sensitive topic that is difficult to discuss. Respondents on the phone interviews may lack confidentiality and feel that they cannot report sexual assaults that involve relatives or family members. In addition, telephone surveying may result in lower disclosure of rape, and repeated victimizations by the same perpetrator have been excluded from the rape estimates.

Overall, the NCVS consistently shows victimization levels higher than those of the UCR

Program. It has been noted that victimization surveys are not inherently more accurate than reported crimes; both sources of data contribute to the scope of violent crime.

Specific Measures of Sexual Victimization

Both the NCVS and the UCR Program have been criticized for narrowly conceptualizing sexual victimization behaviors and for not accurately measuring all the various types of sexual victimization, such as harassment and stalking. Some scholars contend that the uses of victimization surveys that focus exclusively on women's sexual victimization can arrive at a more accurate empirical assessment of the extent of women's sexual victimization. Many of these types of specialized surveys have revealed that sexual victimization is more widespread than that found by the UCR Program and by the NCVS. The following discusses some of the various specific attempts at measuring sexual victimization.

In an effort to measure sexual victimization more accurately, Mary Koss and her associates constructed the Sexual Experiences Survey (SES). This survey was a standardized instrument for measuring rape and a broad range of different types of sexual victimization. The SES instrument used behaviorally specific questions that described specific types of experiences in order to cue victims to report victimizations. Behaviorally specific questions are worded to describe specific acts, such as "the penis penetrated the vagina." It is also important to note, for definitional purposes, that the survey questions were grounded in the existing legal definition of rape/sexual assault. Their SES and modified versions have been used in many subsequent sexual victimization studies both inside and outside the United States.

College Student Sexual Victimization Measures

Much of the specific research to measure sexual victimization, such as the initial studies using the SES and the National College Women Sexual Victimization Study (NCWSV), have been conducted using college student samples. College women are at a greater risk of such victimization, and they are conveniently accessible to many scholars. Like the SES, the NCWSV measured sexual victimization by cuing and screening potential victims with

behaviorally defined questions and then used the NCVS method of detailing the victimization through an incident report. These methods are intended to ascertain a more valid and accurate measure of the types and extent of sexual victimization of college women.

During national-level studies of college women and sexual victimization, the victimization rate is several times greater than rates published by the NCVS. These findings suggested that rape victimization is more extensive than government measures indicate.

National Women's Study

The National Women's Study (NWS), next to the NCVS, was once one of the most frequently cited estimates of the incidence of rape in the United States. This study is somewhat dated as it was a 3-year longitudinal study from 1990 to 1992. Nonetheless, this survey measured and reported rape from a significant sample of American women ages 18 to 34 years. Like the SES, the researchers used behaviorally descriptive questions to elicit victimizations. When comparing the estimates of women who were raped using results from this survey with the NCS data, the NWS estimate was somewhat greater than the NCS estimate. The main limitation of this study was the narrow definition of rape as it measured only completed forcible rape, not other forms of sexual victimization. In addition, this survey did not employ an incident report to "check" or validate respondents affirmative response to victimization screen questions.

National Violence Against Women Survey

The National Violence Against Women Survey (NVAWS) was introduced in 1998 as a household survey on personal safety with a significant sample of women 18 years and older. It includes questions about general fear of violence and about incidents of actual or threatened violence experienced during the respondent's lifetime and annually by different types of perpetrators. The NVAWS estimates revealed that women are victimized at a greater rate than the NWS's lifetime estimate and the NCVS data. These results must be interpreted cautiously as estimations were made between the data sources. The NVAWS also collected data on stalking, which

is a form of victimization that has relatively recently gained public and legal attention.

Challenging Issues

Measuring sexual victimization is an exigent undertaking. Issues of measurement can include identifying the types of sexual victimization, which range from sexual harassment and stalking to sexual assault; how to measure validly and reliably; how to collect accurately more detailed accounts of reported sexual victimization; and how best to increase the sample's response rate. Another challenging methodological issue is how to word questions in a survey instrument that are capable of measuring the legal elements of the crimes being measured so they are fully understood by respondents. Other issues of concern include the sequence of questions and specific words to describe behaviors.

Overall, in the last 35 years, progress has been made as well as growth in the number of research studies trying to measure accurately the extent and nature of rape and other types of sexual victimizations. Given continued methodological weaknesses, victimization measures can provide only an approximate estimate of how much rape and other types of sexual victimization occur to females and males.

RAPE CRISIS CENTERS

Rape crisis centers (RCCs) are probably the oldest community-based intervention programs for sexual assault survivors. Even though they are primarily focused on providing services to rape victims and on educating communities about sexual violence, because they were first conceptualized by feminist activists, one of their initial inspirations was to change a society that encouraged the (sexual) oppression of women. RCCs can operate at different levels: on campus, attached to a particular city, organized at the county level or as a statewide coalition. Today more than 1,200 RCCs exist in the United States, some of them being more than 35 years old. Across the world,

RCCs or a local equivalent can be found in numerous countries, including the United Kingdom, Australia, Norway, France, and Germany, as well as Bosnia, Estonia, Japan, and South Africa. As this entry describes, the history of RCCs is strongly connected to the feminist movement.

Development

The gendered nature of rape as a crime committed most exclusively by men, almost exclusively on women, became a major feminist issue in the 1970s as a hallmark of a sexist society's debasement of women. The women's movement was therefore not only about debating the idea of equality, as many feminist activists were involved in victim's assistance. Indeed, it often happened that victims reporting rape were assailed at trial and that their lifestyle was exposed as a justification for their rape. Reacting to those cases where victims themselves were put on trial, practitioners laid the grounds for the victim's well-being movement. Radical feminists led the way in constructing alternative interpretations of offender-victim relationships and victim experiences with criminal justice procedures, viewing the victim as someone who deserved assistance from the system and not as someone to blame.

Among the many faces of feminist activism, RCCs are probably one of the most visible forms. The first American RCCs emerged in the 1970s. They were created to provide crisis services to rape victims, to inform communities on sexual violence, and to rally forces for social change. At first, RCCs relied on grassroots efforts, as follows: Volunteers gathered at private houses, most of the material was donated, and staff had no professional training in the area of counseling. Both theoretical and practical approaches were eminently political—and politicized—as one considered rape through the prism of power and control relationships and gender inequalities in society. Surely, women involved in RCCs were driven by the desire to help the victims, but part of their motivation may have included politicizing these victims in order to achieve the ambition of overthrowing established power relationships between men and women. Because their goals were wider than simply reforming rape-related official procedures, RCCs were considered by some to be radical feminist organizations since

their members were protesting against power relationships and the existing social order. As Amy Fried pointed out, for radical feminists, building a female-based power structure was believed to be a first step toward a rape-free society.

Being run as feminist collectives, the organization of RCCs was very different from that of traditional service providers. They rejected classic hierarchical organization; they were autonomous and not affiliated with other agencies. It is true that, as members did not always share the same values or the same goals, it may have provoked some conflicts, and some authors suggest it was probably not ideal for the implementation of collaborative working.

Across time, RCCs started to form broader coalitions (e.g., in Pennsylvania in 1975, 10 RCCs joined forces to form the Pennsylvania Coalition Against Rape [PCAR]). Undeniably, coalitions are more powerful, and they are more liable to initiate social or legal reforms. For example, PCAR served as model and inspiration for the creation of the National Coalition Against Sexual Assault in 1976.

In the 1980s, more and more RCCs became professionalized institutions, moving from a helping model based on volunteers' commitment, to a hierarchical organization promoting a counselor-client model. To secure state and federal funding, many RCCs engaged in lobbying or administrative reforms. Because new funding sources became available for agencies providing direct services to other victims of crime, some RCCs expanded into general crime victims centers.

RCCs were strengthened in 1994 when the Violence Against Women Act (VAWA) was signed into law. The VAWA's programs range from policies to encourage the prosecution of abusers to victims' services and prevention programs. This made available considerably more money for the development of RCC services throughout the country and helped strengthen alliances among the police, the court, and victim advocates.

Services Provided

Although the philosophy of RCCs evolved throughout the years, the basic services provided by the centers remain relatively the same as the ones originated in the 1970s. Most RCCs run 24-hour

hotlines; usually people answering the calls are volunteers trained in crisis intervention. Most RCCs also offer counseling services (individual or group counseling and support groups) run by licensed professionals, sometimes paraprofessionals. Most RCCs welcome any rape victims, women, children, as well as men; at times, support for survivors' families may also be dispensed.

One of the most challenging tasks of RCCs involves the training of staff as legal and medical advocates. In this context, advocacy consists in assisting survivors when they try to make their way through both medical services and the criminal justice system. It also attempts to educate staff from those institutions to prevent what is often called "the second rape." The later notion—academically known as secondary victimization—refers to the often-negative treatment rape survivors experience from officials that exacerbates rape trauma. To avoid this kind of trauma, RCCs focus on collaboration rather than on confrontation with local agencies and authorities.

In addition, many RCCs have managed to develop strategies to mobilize their home community. They assist conventional organizations; they make them sensitive and help them to promote anti-rape values. The centers often run educational campaigns, which includes communication materials, public talks, and informative sessions at schools.

Prevention programs can specifically address rape and sexual violence, as well as violence against women in general. Campaigns can focus on educating women not to put themselves at risk, or they can also teach men that they are not to use their strength to hurt others. Some centers also offer self-defense classes. Through the years, RCCs have been remarkably flexible and innovative and most of them have built a community network under the response to rape.

RCCs and advocacy programs often relied on volunteers, especially in the early years. This clearly had several advantages, the first one being to save money. For some people, it also served the goal of educating civilians—and, as a consequence, their families and friends—about the myths surrounding rape victimizations, which could be perceived as an indirect way of achieving a positive social change. Nevertheless, volunteers cannot be expected to have the same knowledge and expertise as hired professionals. As they are not paid,

volunteers do not have regular office hours, they cannot always do follow-up with recent survivors, case management, or on-call shifts to guarantee proficiency and medium- to long-term interactions. Balancing volunteer work and professional services is a systemic problem, as many agencies do not have any other choice than to rely on volunteer staff. However, with the multiplication of Sexual Assault Response Teams and Sexual Assault Nurse Examiners programs, advocacy programs are challenged to provide the same services as paid professionals do.

The Challenge of Evaluation

Even though RCCs have existed for decades, it is only recently that concerns regarding the necessity to evaluate them formally have been raised. Many practitioners and scholars assumed that RCCs helped victims because they were created to do so and stated that was what they were doing. It was as if the centers and their work were unquestionably helpful. However, the reality may be a little more complex.

To assess RCCs' effectiveness empirically, one needs to compare outcomes of victims who received advocates' support with victims who did not. Studies doing so have assessed that victims who worked with RCC advocates experience less distress. Results suggest that advocates are successful in helping victims navigate the criminal justice system and in limiting victim-blaming reactions. Showing how RCCs can help rape victims is one aspect of the evaluation; yet it is far more complicated to determine whether they influence society on a more abstract level with respect to changing culture toward a rape-free society. RCCs have little to no time to devote to this issue, most of their time being devoted to invisible—behind the scene—work. It is indeed extremely complicated for a social movement to show its efficacy.

Although differences exist in respect to what and how much has changed, the desire to empower survivors and educate society to eliminate violence against women is still alive.

RAPE LAW REFORM

Rape law reform has been an ongoing process virtually since women won the right to vote in the early 1900s. Reformers have expressed persistent frustration that despite laws that forbid rape, the crime continues to occur at epidemic rates and yet has remained the most underreported and underprosecuted of all major felonies.

Two major waves of reform, in the 1950s and 1970s, attempted to address the reasons why rape law made cases difficult to prosecute and win. Initiatives during these periods focused on removing unfair legal burdens but were largely ineffective at improving prosecution rates and at reducing incidents of sexual violence. Newer and current reform ideas are aimed at cultural prejudices and

systemic biases against women in general and rape victims in particular.

Past Reforms

Utmost Resistance

In addition to proving forcible sexual penetration without the victim's consent, many states once also required proof that the victim resisted the crime "in the utmost." This not only made prosecution near impossible in most cases, it effectively obligated victims to risk additional physical harm during the crime. Early reforms eliminated the utmost resistance requirement, although jurors still tend to judge victims harshly when they do not aggressively resist their attacker.

The Infamous Judge Hale Instruction

Before the 1980s in most states, judges overseeing rape trials were obligated to instruct the jury that rape was "an accusation easily to be made, hard to be proved, and harder yet to be defended by the party accused, tho' never so innocent." This statement, known as the "Hale warning," has its roots in the common law and was crafted by a judge infamous for his hostile attitude toward women, including his belief that it was not a crime for a man to rape his wife. Sir Matthew Hale, a chief justice in 17th-century England, authored this instruction because he believed that jurors should be extra skeptical of a rape victim's credibility. During reform efforts up to and including the 1980s, states abandoned use of the Judge Hale instruction, although many jurors continue to believe rape is a crime easy to allege and difficult to defend—even as data suggest the opposite is true.

The Corroboration Requirement

Also during the 1970s, states eliminated the requirement that the victim's testimony be "corroborated" or supported by other evidence. Once an element of the crime in many jurisdictions, the requirement that a rape allegation include extra corroboration rendered cases impossible to prosecute because the crime typically occurs in private, the defense claims the act was consensual,

and the only evidence of nonconsent is the word of the victim. Abolition of the corroboration rule meant that more cases could proceed to trial, and yet juries continued to render not guilty verdicts where there was no corroboration of the victim's testimony.

The Marital Rape Exception

In most states, the crime of rape was originally defined as occurring only against a person who was "not the spouse" of the defendant. This definition meant that rape of a wife by her husband was legally permitted. Reform efforts to eliminate this exception have largely been successful, although some states have moved slowly. The last state to eliminate the spousal exception did not do so until the 1990s. Although the exception itself is no longer part of the black-letter law, the rape of one's wife is rarely prosecuted and is still treated as a minor crime in many states such that it is either more difficult to prove or is subject to lesser punishment than the rape of a nonspouse.

Rape Shield Laws

Reformers in the 1970s celebrated the passage of new laws designed to prohibit the use of a victim's sexual history as evidence at trial. This was intended to prevent a common trial tactic whereby the defense would suggest to a jury that a sexually active woman should be presumed to have consented to the defendant's conduct because she had a practice of engaging in consensual sexual activity in the past. Even if this strategy was not explicit, the mere mention of a victim's sexual activity would easily lead to an acquittal because the jury would blame or dislike the victim based on her past behavior. The enactment of laws to prevent the use of this evidence was hailed as a victory, however, in most states, the legislature tacked on exceptions to the rule such that shield laws were ineffective from the date of enactment. For example, one common exception expressly allows for sexual history to be admitted so long as it involves actions between the victim and the defendant. For married victims raped by their husbands, or victims raped by a long-time intimate partner, this exception rendered the rape shield law not just meaningless but harmful. Before shield laws, a

married victim at least had an opportunity to argue that her past sexual conduct with her husband was irrelevant. Shield laws essentially created a legal presumption of admissibility where one had not existed previously.

Across time, rape shield laws have produced mixed results. For judges who needed education to understand why prior sexual conduct evidence was irrelevant and unfair, the laws helped them to be more mindful. But many judges continue to allow the forbidden evidence to be used at trial not only because of personal and cultural prejudice but also because a victim cannot appeal a judge's decision that violates the shield law. Although prosecutors can appeal certain judicial rulings, they are typically disallowed to challenge a decision involving rape-shield issues.

New Reform Ideas

Abolish Rape-Shield Laws

The failure of shield laws to serve their intended purpose has led to new discussions about their efficacy and possible outright repeal, at least in states where they are proving to be more harmful than helpful. Reformers are instead proposing that victims be represented by private attorneys (the prosecutor is not the victim's personal lawyer) who can argue to the criminal judge that the victim's past sexual conduct is irrelevant, and that excluding it as evidence at trial helps to preserve the constitutional rights of all adults to engage in lawful consensual sexual activity. Reformers argue that with a constitutional rather than a mere statutory argument on the victim's side (statutory laws are far less weighty than constitutional rights), victims' sexual privacy will be better protected and the integrity of the trial itself will be free from the unfair taint of irrelevant, personal, and unduly prejudicial information related to the victim's sex life.

Eliminate Element of Force

In nearly every state, to prove the crime of rape, the prosecutor must show not only that penetration occurred without the victim's consent but also that it was done with "force." Since the ostensible purpose of rape law is to preserve the personal autonomy and bodily integrity of women, reformers are

asking why it is not enough to merit criminal prosecution that penetration occurs without consent, irrespective of the use of force. In the context of theft crimes, when money is taken without consent, the crime of larceny has occurred. If force is also used, the more serious crime of robbery is charged. But when bodily integrity is taken without consent, there is no crime in the absence of additional force beyond that which is necessary to cause penetration without consent. Reformers are now proposing a new law titled “rape without force” or “non-forcible interference with sexual autonomy.” If force is also used, a more serious charge can be brought, but if rape law is to be effective at protecting bodily integrity and personal autonomy, then the nonconsent of the victim, alone, should constitute criminal sexual conduct.

Prior “False” Allegations

In most states, the defense is authorized to inquire about, and to use, evidence that a rape victim made a prior false allegation of rape. This special rule does not typically apply to other types of cases. For example, if a victim is robbed, there is no rule that allows the defense to inquire about, and to use as evidence at trial, the fact that the victim made a prior false claim of robbery—or rape—or anything else. The rule generally applies only to rape victims, and only in rape cases, even though false claims related to insurance fraud and other money-motivated crimes are far more common than false claims of rape.

It is tempting to assume that a prior false claim reveals something about a victim’s credibility, but if this is the premise behind the rule, then it should apply to victims of all crimes, not just rape. And even so, the law in all states requires that the judge balance the prejudicial value of such information against its probative value such that allowing the jury to hear about a past lie will elucidate rather than distort the truth. Reformers are now focusing on how to make judges strike a more fair balance such that evidence of a past false claim is excluded unless it will prove materially helpful to the truth-finding function during trial. For example, judges are being advised to appreciate that victims of domestic violence often recant sexual abuse claims, not because the claims are false but because they fear for their lives. Yet recantations are often

treated as prior “false” claims. Reformers hope to inject into rape trials a better understanding of the nature of prior false claims, alongside an argument that the rule not be applied exclusively to victims of sexual violence.

Mental Health Records

In some states, the privileged therapy/counseling records of rape victims are routinely disclosed to the defense, simply for the asking. In other states, the defense must make a showing of need, and then a judge will screen the records to determine whether they contain evidence that bears on an issue legitimately in dispute at trial. In either type of jurisdiction, a defense request for similar records of a robbery victim will be summarily denied as an undue interference with a victim’s privacy rights. Thus, as with the prior false claims rule, reformers have begun to challenge this practice as unfair treatment of rape victims. To make the argument, lawyers have started to appear in court to object on behalf of victims as well as of therapists and hospitals where the records are kept. The act of sending an attorney to court to object is often enough to protect a victim’s privacy. But often these third-parties cannot afford to hire counsel, and in many cases, the victim is not even aware that her records have been requested. Reformers are working to provide free or low-cost legal services to ensure that proper objections are made and that the privacy and due process rights of victims are respected.

Where to Go for Meaningful Reforms

Early reformers went to the legislature in the hope that things like removing the marital rape exception or enacting a rape shield law would repair systemic mistreatment of victims. But 30 years later, the same data on incidence rates and failure of prosecution efforts shows that those initiatives made little difference. One reason seems to be that although women worked together to lobby for legislative reforms, they had no opportunity to ensure proper enforcement of those laws during criminal trials where women as a class, and in their capacity as individual victims, had no voice. New reformers have shifted reform efforts away from the legislature and toward the judicial and executive branches of government.

The Judicial Branch

Using due process arguments, victims are teaming up with private lawyers and public interest advocacy organizations to demand fairer treatment in criminal cases. Although many judges will question the victim's standing to be heard as a nonparty in a criminal trial, if the system interferes at all with the victim's personal rights (as when the defense seeks access to counseling records or asks probing irrelevant questions about her sexual history), the victim has an absolute right to be heard under the law of due process.

Reformers have also begun to focus on the jury system, insisting that the people who sit in judgment during a rape trial need to be better screened so that those with prejudicial ideas about women in general or rape victims in particular are excluded from the jury. This type of screening is already being facilitated as a matter of course on issues of race and ethnicity, typically on behalf of the accused. Rape law reformers are now advancing gender-based arguments to ensure that the integrity of the process is not tainted by unfair prejudice against the victim.

Similarly, judges are being asked to instruct jurors to be mindful of their own biases against women and rape victims when they retire to the jury room to deliberate on the question of guilt.

Another reform effort in the judicial branch involves the filing of amicus (friend of the court) briefs in appellate cases on behalf of victims and women. Appellate courts often render decisions that create new law or reflect a change in legal policy regarding rape law. Amicus briefs can help to inform appellate courts as to the likely impact of their decision on society, particularly the lives of women, children, and sexual violence victims.

Finally, reformers have been developing court-watch programs that literally place concerned citizens in the audience of courtrooms where rape trials are being handled, to "watch" over judges and make a record of any unfair treatment of the victim, the case, or the issue.

The Executive Branch

As the executive branch official responsible for the prosecution of sexual violence, the prosecutor/district attorney has a duty to make decisions that reflect appropriate respect for the seriousness of

the sexual violence. Reformers have begun to recognize the importance of the prosecutor's role and are becoming politically mobilized to hold prosecutors accountable. For example, during an election year, reformers will insist on full disclosure of how the pie of public resources is being spent on rape trials, and what happens to the cases that are reported to the prosecutor's office. How many reports are accepted for prosecution? Declined? What happens to the ones that move forward? How many end in acquittal? Plea bargain? What punishments are handed down in the end? Reformers are demanding annual "report cards" and promising to prevent the election of candidates who refuse full public disclosure of relevant data on prosecutors' handling of rape cases.

Reformers are also starting to ask prosecutors why sexual violence is not treated as a hate crime. In many states, the law allows prosecutors to seek an enhanced punishment when a crime is committed based on hatred directed at a person because of membership in a protected class, such as race or gender. Yet most prosecutors refuse to bring such charges in rape cases. New reformers are hoping to influence social and legal discourse such that sexual violence is routinely conceived and charged as a civil rights issue, at least for recidivist offenders.

The Legislative Branch

Although many legislative initiatives provide only superficial solutions to cultural and systemic problems in rape law, the legislature can help ensure that victims are not mistreated during the processing of criminal rape cases.

For example, reformers have asked legislators to enact laws to provide better oversight and accountability to redress the misconduct of defense counsel and defense investigators in their interactions with victims. Current practice provides almost no options for a victim who suffers intimidation or other strategic attempts to discourage her from participation in the processing of a rape case.

The legislature is also in a position to enact new laws that mandate victims be advised of their rights at the outset of a criminal investigation, such as the right not to reveal any personal or private information unrelated to the investigation, and the right not to speak with defense counsel or a defense investigator. Too often, victims disclose irrelevant

personal information because they do not understand the implications of revealing the information, and they have no way of knowing how the defense may then use it against them either before or during trial. By ensuring that victims are aware of their rights at the outset of an investigation, reformers hope to empower victims, minimize intimidation tactics, and enhance the overall fairness of rape trials.

RAPE MYTHS

The stereotype of rape is that it is a violent attack by a stranger, leaving the victim—who fought

back—injured. Most rapes do not fit this pattern; generally victims/survivors know their assailants. For this reason, many (including victims) have trouble accepting forced sex between acquaintances as rape: It doesn't seem to fit the definition. Victims who cannot put the name “rape” to what happened are less likely to report to the police or seek counseling.

Throughout Western history, most policy makers have agreed that “rape” is a felony crime that warrants severe punishment. A notably chaste woman raped by a gang will almost always receive support. However, when the accused offenders are not obviously violent strangers, the stereotype is challenged. At that point, understanding the offender as a “criminal” becomes difficult, and this shifts the blame to the victim, as it is often thought that a nonstereotypical victim must have somehow caused her victimization.

Because of this stereotype, anti-rape measures tend to be based on the belief that rapes are mainly committed by strangers. For example, universities invest heavily in removing bushes that could hide rapists, installing blue light phones, hiring security, and providing expensive escort services. Women are constantly warned never to be alone at night, to guard their drinks with extreme vigilance, and to be trained in measures to fight off stranger physical attacks.

However, every measure from police records to victimization surveys to government-sponsored research reports has shown that as many as 80% to 90% of offenders were known to the victims. In other words, this popular conception about rape does not reflect the reality of the situation. Such popular misconceptions are often called “rape myths,” because they are powerful stereotypes that can have a profound impact on perceptions of rape and the treatment of victims/survivors and offenders both within and outside of the criminal justice system. According to Martha Burt, rape myths are beliefs about the act and/or the parties to the action that are false or based on stereotypes. Kimberly Lonsway and Louise Fitzgerald define rape myths; although believed by many individuals, they are typically false and are used to justify sexual aggression by men.

Of course, men are also the victims of sexual assault, generally by other men. However, since virtually all studies find a low rate of sexual assault

reported by men, victims/survivors are referred to here as “she” and offenders as “he.”

Types of Rape Myths

Rape myths can blame the victim for her victimization, relieve blame from the offender, and/or trivialize the rape itself. Victim-blaming rape myths imply that women are somehow at fault for their own victimization. For example, “She wanted it at the time but changed her mind the next morning” or a suggestion that the victim is lying about the rape for revenge or to excuse a sexual liaison to a husband, boyfriend, or parents. Other victim-blaming rape myths suggest the victim somehow provoked or encouraged her own victimization. Here, some might claim that rape only happens to certain kinds of women, like those who put themselves in dangerous situations, such as parties where drugs and alcohol will be served, or who dress a certain way. Sarah McMahon adds that there is a perception of rape invulnerability of female athletes; many believe that these strong women cannot be victims of rape.

Other rape myths may serve to relieve offenders of blame. Some think that rape may only be a misunderstanding of consent: A common belief is that she said “no” in a playful way but really meant “yes.” Why, then, a woman who “meant yes” is pressing felony charges remains a mystery, solvable only by those who believe this myth. Another rape myth holds that rape may be accidental, for example, in instances where both the victim and the offender are intoxicated or when men sometimes “lose control.”

Rape myths may also serve to trivialize the rape. A particularly damaging claim is that many sexual assaults do not really harm the victim. Others—even victims themselves—might believe that some rapes (including those that fit the criminal code definition of first-degree sexual assault) are simply “bad dates” because they are not stereotypical violent stranger attacks.

Neutralization

Gresham Sykes and David Matza posited that most people who engage in crime believe that crime is wrong, so they develop rationalizations to make the crime more acceptable. In effect, they

neutralize the deviant behavior for themselves and anyone who agrees with them. Three of their Techniques of Neutralization—denial of injury, denial of victim, and denial of responsibility—are particularly relevant to understanding rape myths.

Denial of Injury: “Nobody got hurt.”

To Sykes and Matza, a crime (like rape) can be explained away by claiming that the victim was not injured. For example, promiscuous women or prostitutes are not “really” raped; the rape myth holds that it was a “bad date” or “business deal gone bad”—or even that the victims are not really people who can be injured, as Jody Miller and Martin Schwartz describe.

Denial of Victim: “She had it coming.”

Rape myths deny the victim; that is, they perpetuate the belief that the victim was at fault or deserved the assault. For example, some believe that prostitutes or wives cannot be raped, as they have, by definition, given irrevocable consent. Another common misperception is that an intoxicated victim deserves her fate for having made herself vulnerable.

Denial of Responsibility: “It wasn’t my fault! She wanted it!”

Rape myths serve to shift blame from the offender to the victim, so that the offender is not held accountable. A common defense to the charge of rape is that the sex was consensual and the offender was not at fault. Some people believe that men can temporarily lose control and not realize what they have done until after the rape. Of course, there is no place in law where this is a legal excuse.

The Criminal Justice System

Rape myths have implications for criminal justice processing. Victims, offenders, and criminal justice officials who believe in rape myths may not recognize that a crime was committed. Within the criminal justice system, police may be less inclined to take a victim seriously, write a report, or make an arrest. Evidence exists that rape myths guide police follow-up investigations. Police commonly classify

subjects and situations into “typical” categories. With rape, stereotypes identified by rape myths may guide decision making, especially when officers have large caseloads, the victim is unlikely to follow up repeatedly, and the case does not provide much information. With “suspect rapes” involving certain women (e.g., lower class or victims falling into certain categories), victims are discredited and allegations of rape are often considered false.

Perhaps the most dangerous impact of rape myths is when they interact with police misconduct. Peter Kraska and Victor Kappeler document police sexual violence against women, which can range from improper strip searches to using their position of authority to force women into sex. They suggest that such officers may believe that intoxicated women in bars are of lower status and are worthy targets of rape, in effect neutralizing their own behavior. Even if police make an arrest, prosecutors may decline to pursue charges if they blame the victim for her own victimization. When a prosecutor pursues charges, myths may affect jury selection or the jury may not convict. Jurors often take into account factors such as gender or offender appearance, and they often rely on rape myths.

Prevalence of Rape Myths

Rape myths are not confined to the criminal justice system. In an enormous literature, studies have shown that men, athletes, and students are more likely to hold ideas supporting rape myths. It is progressively more difficult, however, to locate these populations as many men today know that the “right answer” is to deny holding such beliefs. McMahon has demonstrated that survey measures may not show such beliefs, but that focus groups and individual interviews have revealed subtle and pervasive rape myths.

The Media and Rape Myths

Mass media has long been suspected of forming and perpetuating stereotypes. Broadcast media in particular only present rare cases of certain types, which perpetuates stereotypes. In an attempt to sell stories, facts are presented in a way that grabs attention. To show the effect of the print media on attitudes, Renae Franiuk and colleagues ran a

randomized experiment, finding that those exposed to fictitious rape myth endorsing stories were more likely to believe an alleged offender was innocent; respondents exposed to rape myth challenging articles were more likely to believe an alleged offender was guilty. A sign that the media are an important socialization tool can also be seen in that even among women, those who watch more general, daily television shows are more likely to hold some rape myth-supportive beliefs.

Eliminating Rape Myths

Rape myths are prevalent—although they may be subtle—in society and have implications on how victims are treated. Schwartz and Walter DeKeseredy call for a national program targeted at patriarchal attitudes supportive of violence against women. A national campaign may be the first step in eliminating rape myths.

RAPE SHIELD LAWS

Rape shield laws are statutes or court rules that mostly date from the 1970s and are virtually universal today. Most states adopted shield provision laws as part of the more general reform of rape laws. The rationale for reforms originated from feminists, social scientists, and legal scholars, who stated that laws and rules of evidence unique to rape encouraged criminal justice professionals and jurors to use extralegal factors as a basis to establish guilt or innocence. A rape victim's past sexual conduct and credibility was at the center of these laws. The prevailing thought was the more chaste a woman is, the more likely she would have avoided a sexual advance and to have a justifiable rape allegation. In contrast, an unchaste woman was more likely to have consented to the sexual acts that she would later claim amounted to rape. Furthermore, this crime, unlike others crimes, required there be corroboration of the woman's claim (e.g., reasonable resistance). Legislatures did assent to excluding the chastity requirement by allowing rape shield provisions to limit the extent to which defendants (and their lawyers) could introduce evidence of a victim's sexual history in rape trials.

Ideologically, these evidentiary laws were enacted to prevent secondary victimization by protecting the privacy of the victim and limiting the prejudicial practice of discrediting the victim's rape allegations based on his or her sexual history. Research has suggested that without these in place, victims are deterred from reporting the offense and from participating in the prosecution. Thus, the laws intended to make it more likely for victims to report the actions and not worry about self-incrimination or

past conduct. This is of importance since research has shown that although rape is one of the most under-reported crimes, acquaintance rape is often perceived as less serious than rape between strangers.

Although rape shield laws preclude admission of other sexual experiences, most state statutes and rules do admit evidence of sexual history. Specifically, sexual history between the plaintiff and the defendant is admissible if the defendant provides information regarding pregnancy, disease, or the source of semen. Other states allow sexual history evidence for proving consent and for impeaching the complainant's credibility, and 11 state rape shield laws have "catch-all" exceptions. These exceptions permit the introduction of evidence, even that which normally might be barred by a rape shield law, if the defendant can demonstrate that sexual history evidence is relevant in establishing innocence.

Clearly, the controversy regarding rape shield laws presents conflicting demands. On the one hand, research suggests that strong provisions help protect the privacy and dignity of victims while consequently encouraging victims to report rapes and reduce the ability of defendants to erode the victim's credibility. However, other research maintains that strong shield laws also limit the defendant's Sixth Amendment rights in their ability to establish a complete defense strategy. To date, the constitutionality of these laws has been upheld. Specifically, courts have held that the state's interest in protecting sexual assault victims from harassment and humiliation at trial, as well as the highly prejudicial effect such evidence may have on a jury, outweighs the rights of the defendant. In fact, some courts have expanded the use of rape shield laws beyond the original intent.

Expansion of Rape Shield Laws

Although the goal of the reformers to shift the focus of the trial from the victim (e.g., sexual history) to the defendant's actions has proved to be difficult, research has shown that recent changes to the rape shield laws have been expanded to include other evidence that legislatures deem prejudicial. One example is the clothing of the victim that the defendant tries to introduce to show that the victim consented to or asked for the sexual contact. State statutes that do restrict the

admissibility of clothing, however, make exceptions where it is introduced to show a struggle (or lack thereof) or proof of the presence (or absence) of bodily fluid, such as semen or blood. Rape shield laws have also been expanded in most states to protect victims of all sexual offenses, regardless of the victim's age or sex.

Rape Attribution Studies

Most rape attribution studies using rape scenarios and college students as subjects agree that a woman's past sexual life should not be an issue in a rape case. Indeed, research has shown that to quiz a woman who says she was raped about whether she has had two or more sexual partners is not only cruel and degrading but irrelevant to the question of whether she consented to sex. Other research uses perceptions of criminal justice professionals to determine the likelihood of sexual history evidence being admitted at trial. Regrettably, informal norms about sexual history, what the rape shield law intended to circumvent, are still highly relevant to case outcome.

Impact

Evidence suggests that the primary beneficiaries of rape law reform have been women who are raped by strangers. Specifically, cases with aggravating circumstances (e.g., weapons and serious injuries) have a greater likelihood of prosecution and conviction. The law has had little or no impact on victims of nonstranger rape. In fact, some argue that rape law reform is more symbolic than productive in nonstranger cases. This number is high, as research reports 80% of rape victims know their attackers. Clearly, greater effort is needed to affirm that changes are actually implemented and practiced.

RAPE TRAUMA SYNDROME

Rape trauma syndrome (RTS), originally theorized as an acute stress reaction to the threat of being killed while living through and surviving completed or attempted rape, has evolved into three overlapping but distinct bodies of literature regarding psychological trauma. This entry provides a definition of the syndrome as originally theorized and its value and limitations, key advances in knowledge regarding the human trauma response as related to epidemic yet minimized prevalence rates of sexual victimization and resultant traumatization, a brief comment on use of RTS in the prosecution of rape and sexual assault, and some suggestions on prevention.

Original Definition

Rape is the forcible entry of one person into the most intimate parts of another person's body with an aim toward imprinting the victim's soul against her or his will. Whether or not the victim sustains visible bodily injury—and most do not—rape is an act of profound cruelty experienced as abject powerlessness, a sexualized act of dominance that reduces the victim's sacred personhood to an inanimate object to be used at the sole discretion of the perpetrator. Until the mid-1970s in the United

States, rape and other forms of sexual violence were culturally (mis)understood and purported to be not much more than a nuisance, predominantly nonconsequential for the victim, other than, for female victims, lowering their prospects or value as Wife. Rape and other forms of sexual victimization are currently considered by criminal justice authorities as among the most severe and underreported violent crimes in America today.

RTS was originally theorized, in 1974, by researchers Ann Wolbert Burgess, a psychiatric nurse, and sociologist Lynda Lytle Holmstrom, to describe the patterned post-assault experience of victim/survivors of completed or attempted rape, which they characterize as a traumatic stress reaction to the threat of being killed. This first empirical investigation on victims' responses to rape used a convenience sample of all persons admitted to an urban hospital emergency department for treatment for rape within a 1-year period. Of the 146 individuals who were treated, which included children, adolescents, and males, 92 interviews from the adult female rape victims were analyzed. The researchers detailed the pattern of emotional and physical distress, coping, and healing victim/survivors go through while suffering the effects of victimization, immediately after the violation and over time. RTS, as described by Burgess and Holmstrom, consists of two post-assault stages of recovery: the *acute phase* followed by the *reorganization phase*, both of which involve profound psychological, physical, behavioral, and social consequences that wield the capacity to disrupt and alter the victim/survivor's life, forever, to varying degrees.

The acute phase of RTS occurs immediately after the sexualized assault and generally lasts days to weeks, although victims vary as to the amount of time they experience it; often acute phase symptoms overlap with the symptoms of the long-term process of reorganization. Similar to the shocking and overwhelming experience of victims who have survived other types of inescapable life-threatening situations, the acute phase is marked by fear of physical injury, mutilation, and death, and it is characterized as radical disorganization of multiple aspects of the self and daily life; thus, it is also referred to as the *disruptive phase*. The primary task of this stage of recovery is to quell the crisis of intrapsychic disequilibrium the rape triggered in the victim so she might feel safe in and familiar

with her own body—its sensations, effects, and behavior—again.

The impact of rape in the acute phase is manifest in one of two styles—*expressed* or *controlled* reactions. In the expressed reaction, the victim shows outward signs of fear, anxiety, shock or sense of disbelief, anger, apprehension, guilt, shame, embarrassment, humiliation, degradation, feeling dirty, self-blame, revenge, and panic. Behaviorally, the expressed reaction may manifest as crying, laughing, screaming, sobbing, joking, tenseness, shaking, restlessness, and pacing. Within the controlled-type of reaction, the victim masks or hides her feelings, displaying little overt outward response, and may appear calm, composed, disaffected, numb, subdued, bewildered, sedate, or stifled. Controlled behaviors mask the serious psychological wound the rape victim has endured and are likely to be an attempt to suppress hidden inner chaos. As a result of the range and intensity of feelings experienced, victims are prone to mood swings and may alternate between the responses, surprising the victim/survivor and confusing those around her or him not familiar with rape trauma.

The acute phase also includes somatic, cognitive, and behavioral reactions. Cognitive reactions include being “haunted” by intrusive thoughts regarding the incident and how the victim could “undo” it as well as sleep pattern disturbances, such as difficulty falling and staying asleep. Somatic reactions include general fatigue and an overactive startle response; physical trauma caused by bruises, tears, abrasions, and depending on the specifics of the incident, genitourinary disturbances such as infections, vaginal discharge, tearing, and/or soreness, anal bleeding, tearing and/or soreness in the rectal area, irritation of the mouth and throat when forced orally; skeletal muscle reactions such as headaches, general aches, and soreness; and gastrointestinal irritations such as nausea, vomiting, and/or disturbed eating patterns. Those with a preexisting condition, such as alcoholism or psychosis, may experience a reactivation of previously controlled symptoms; Burgess and Holmstrom refer to this as a “compounded reaction,” which may complicate movement into and resolve of the reorganization phase of recovery.

The acute phase is followed by the long-term reorganization phase during which the survivor seeks to make sense of the assault, integrate the

traumatic experience into his or her overall life experience, and rebuild the rape-resultant shattered beliefs about the world, other people, and the self. The primary recovery task in the reorganization phase, which can last from weeks to years and beyond, is restoring order to the survivor's lifestyle and daily living practices and reestablishing a sense of self-efficacy and control in the world. The duration of the reorganization phase varies, because of factors such as the age of the victim at the time of the incident, personality and coping styles, whether the violence was disclosed and when, the immediate reactions of those told, and the overall social and emotional support available and given to the survivor.

Until the trauma is integrated, the reintegration phase is characterized by changes in lifestyle, continued sleep disturbances, and dealing with significant psychological distress. Lifestyle changes are defensive reactions taken to feel safe again (e.g., withdrawal from familiar people or social places once frequented; installing a security system; compulsively checking locks and windows; changing apartments, jobs, schools, or phone numbers; and making new friends). The survivor in the reorganization phase may still be dealing with physical issues from the victimization (e.g., pregnancy, injury, scarring, and/or other physical issues). Burgess and Holmstrom reported that the survivor must contend and work through significant psychological issues in the integration phase of recovery (e.g., nightmares, depression, suicidal ideation, phobias, or overgeneralized fears directly related to a specific aspect of the assault), which continue to disrupt victim/survivors' lives until they are able to make meaning of their victimization and to integrate its consequences into their overall life experience.

Strengths and Limitations of Rape Trauma Syndrome

Rape, up until the 1970s, was conceptualized in criminal justice and legal realms, social science literature, as well as other popular cultural arenas as a rare phenomenon, committed primarily by strange aberrant males, without much consequence to the person raped, and that which warranted concern for the accused rather than the victim/survivor. The widespread prevalence and destructiveness of these gender-biased myths is well documented, as is their result in a deflection of attention

away from the behavior of the perpetrator and toward the behavior of the victim/survivor.

The considerable value of Burgess and Holmstrom's landmark descriptive theorization of RTS is that it (1) demonstrated that rape is a terrifying event that triggers the human trauma response; (2) suggested inaccurate understanding of (sexual) trauma has significant consequences on victims' subsequent behavior; (3) provided the means for prosecutors to explain behavior thought by jurors to be inconsistent with how a "real" rape survivor would/should behave; and (4) stimulated an extensive body of empirical investigation on sexual trauma challenging entrenched social denial and distortion of the subject.

As the oeuvre of traumatic stress and sexual victimization literatures have grown, however, RTS has been critiqued on the grounds that (1) original study findings have not been replicated by voluminous subsequent investigation in that victim responses vary more widely than reported thanks to several increasingly known factors (e.g., social support), although the general recovery phases and their tasks are operative; (2) RTS in many instances meets the criteria for the more inclusive diagnosis of acute stress disorder (ASD) or posttraumatic stress disorder (PTSD) and is not found in any edition of the *Diagnostic Statistical Manual of Mental Disorders*, the standard diagnosis reference guide for psychological conditions; (3) theoretical constructs, specifically the "compound reaction" and "hidden" versions of the syndrome, are unclear and have been subsequently refined as a complex traumatization, the result of criminal revictimization and/or multiple traumas, and the fact that many victim/survivors never label their experience using the criminal justice terms *rape* and *sexual assault* because of their familiarity with the perpetrator, or the absence of weapons or (overt) force; and (4) the term has evolved to include multiple meanings, which is particularly problematic when used for forensic testimony in criminal prosecutions.

Key Advances in Knowledge of Sexual Victimization and the Human Trauma Response

Since the late 1980s, large-scale, population-based public health and criminal justice research investigations have challenged myths emphasizing rarity

and strangeness with regard to sexual victimization: 18% of adult women and 3% of adult men report having experienced rape, completed or attempted, in their lifetime; 25% of girls and 16% of boys report having experienced some form of sexual abuse before age 18 years; and many populations have higher prevalence rates. Most of these victimizations are committed by males known to the victim/survivor as family members, intimates, peers, acquaintances, and trusted authority figures. Sexual violence on a scale this large can only exist within a culture that supports it.

Human beings, on the whole, seek to avoid pain—including bearing witness to the anguished pain of others—particularly when lacking a framework for understanding. As such, the human trauma response is a dialectic characterized by an involuntary movement between the expectation of danger—a “hypervigilance” taking the form of intrusive, uncontrollable body memories, flashbacks, nightmares, and anxiety during wakefulness—and an emotional numbing—a “construction” presenting symptomatically as denial or an indifference to pain, lack of empathy, difficulty expressing feelings, and abhorrence of intimacy and tenderness. PTSD is the psychiatric diagnosis for this symptomatology when it lasted beyond a 3-month period. This dialect, however, operates on individual as well as societal levels, with rippling individual and social consequences.

Judith Lewis Herman’s seminal work, *Trauma and Recovery*, posits the primary experience of psychological trauma—whether instigated by human disregard, malice, or a natural disaster—is one of profound disempowerment of self and disconnection from others. Hallmark characteristics are feelings of shame, stigma, isolation, and when human instigated as in sexual victimization, a deep betrayal of trust, of both self and other. Trauma significantly impacts interpersonal attachments and the ways people relate to and perceive the victim/survivor, as well as the way that the victim/survivor relates to and perceives others. Although true for all forms of traumatization, this is particularly true for sexual trauma caused by harsh cultural misconceptions and victim-blaming attitudes and institutional practices, which result in significant negative impact on victim/survivor disclosure and help-seeking rates, intervention treatment efforts, and criminal justice reporting and prosecution rates, which are notoriously low.

Use in Legal Context

Defense attorneys in rape and other sexual victimization cases seek to capitalize on the general public’s uneducated belief in gender stereotypes and rape myths—which are expressed in jurors’ victim-blaming attitudes. Since the early 1980s, prosecutors have used RTS or descriptions of the impact of rape to explain common victim behaviors in an attempt to assist jurors in sexual violence prosecutions by countering the common myths and stereotypes that consistently hamper these prosecutions.

At this point in history, legal experts strongly advise against using expert testimony that includes RTS for the limitations discussed above. Even when RTS has been admitted into court jurisdictions by passing various federal and state rules of evidence regarding the introduction of scientific testimony, since the purpose of the testimony is to provide an accurate context for which jurors can evaluate a victim’s behavior in relation to the facts presented, it is recommended that testimony focus on descriptions of myths surrounding sexual violence, the dynamics of sexual victimization, and the common victim reactions in relation to behavior. Furthermore, RTS is not a recognized psychological diagnosis, although it is often considered a subcategory of PTSD; therefore, testimony using such language is vulnerable to attack by defense attorneys or to be overturned by appellate courts on the basis of an improper foundation to introduce such testimony.

Prevention

Research in the area of resiliency to the long-term effects of traumatization is increasingly highlighting the role of “social support.” Effective intervention to mitigate traumatization and revictimization necessitates alleviating social shame for victim/survivors so they can get help and holding perpetrators responsible for their actions in courts of law and other social venues. Primary prevention of rape and sexual trauma—that is, stopping it before it happens—necessitates changing key social norms that contribute to the sexual victimization of women, and men, and gender-based violence in general.

RATIONAL CHOICE THEORY

Rational choice theory (RCT) originated partly in response to a growing interest among researchers, policy planners, and practitioners of criminal justice in the 1970s in focusing on crime itself as a central unit of analysis so that something might be done to reduce the impact of crime in the “here and now.” In essence, the rational choice approach seeks to understand how crime happens, without necessarily needing to document why. Derek Cornish and Ronald V. Clarke, both researchers with the Home Office in England, are considered the first to bring rational decision-making perspectives into mainstream criminology. While examining youths released from detention after what seemed to be successful interventions during their custody (e.g., the youths did not violate rules, were sociable, and otherwise exhibited good behavior) some reoffended after release, whereas others did not. This led Cornish and Clarke to consider the impact of the specific situation (environmental factors) in which the youths found themselves as

part of the explanation. This observation parallels the ecological work of the Chicago School that observed that people seemed to leave behind their criminal involvement when they left the social and economic pressures of the downtown core and moved—when they could—to the more affluent suburbs. Here, as with the youth Cornish and Clark observed later, they were the same people but in a different environment, which therefore resulted in different levels of criminal involvement.

This practical focus runs somewhat against the prevailing wisdom that the key to preventing crime is to understand why people become criminal and then design and implement preventive programming of those at risk of becoming criminal, and treating those that already were. At its core, the rational choice perspective posits that, for most offenses, we are missing valuable opportunities for crime reduction if we ignore the role of individual decision-making processes that lead some to commit crimes, whereas others in similar settings and contexts do not. The importance of situational specificity is a defining characteristic of this theory.

Assumptions and View of Human Nature

The main assumptions that RCT requires to be true, or at least mostly true, for most situations and individuals are as follows. First, it is in human nature for us to pursue any given task with a mind to its accomplishment with the least amount of effort, regardless of its morality or universal acceptability. Second, such objectives are pursued within a rational context that prioritizes potential actions against expected costs and benefits (i.e., risk vs. reward). If the benefits outweigh the costs, then the action is at least, on its surface, worth considering. Third, an iterative feedback loop is created that helps process these cues, feelings, and expectations. In this rational calculus, individuals interpret cues from their environment situation and, in a more or less intentional way, apply these to their understandings of past outcomes from previous decisions made in similar contexts. Fourth, although not a formal demand, it is expected that the bulk of decisions will tend to be made in furtherance of self-interest. Fifth, offenders are remarkably similar to nonoffenders, and the former do not typically decide to commit a crime.

Application

Rational choice theory is one of the core theories in what is often referred to as environmental criminology. Along with routine activities theory (RAT) and pattern theory (PT), the rational choice perspective sets out the basic push/pull factors that are thought to be of central importance to understanding crime events. RCT is particularly important in environmental criminology as it serves as the link between the more meso- and macro-levels of analysis used by RAT and PT.

Rational choice theory provides researchers with a structured approach when thinking about the environmental and the social factors that allow us to exploit opportunities to both encourage people to do the right (sanctioned, legal) thing while impeding the ease with which the wrong (unsanctioned, illegal) thing can be done in any given context. In this regard, it works hand-in-hand with situational crime prevention (SCP) schemes. By understanding something of the decision-making process of most offenders, it is possible to identify the largely patterned nature of crime opportunities and make them less suitable, lucrative, or enjoyable via a mixture of environmental planning and product design efforts.

Taking seriously the settings in which offenders and nonoffenders alike operate—that is, how we all go about our daily routines—is the starting point. To reduce crime opportunities, the RC approach would attempt to introduce measures on a micro-scale that

1. increase the risks associated with a criminal act,
2. reduce the potential reward for its completion,
3. interrupt the ease with which the offense can be committed,
4. remove the excuses available to the offender, and
5. reduce provocations or temptations that may prefigure criminal behavior.

SCP generally, and crime prevention through environmental design in particular, promotes strategies that exploit the physical and the social environment to effect these five outcomes. Increasing the risks associated with an offense is difficult as it requires the situational cues to stack up against any

noted benefits in the minds of the potential offender. Signage in mass transit stations posting the number of persons caught shoplifting in the past year would be an example of trying to interrupt criminally intentioned offenders from attempting such an act in the current setting. Similarly, warnings of security patrols or alarms may also serve as disincentives to burgle the premises. Minimizing rewards complements the increasing risks strategy in an obvious way. Consider the entertainment systems in most newer vehicle models, where face-plates, or similar devices that are easily removed by the owner when unattended, make stealing the music player of limited or no value. In addition to adjusting the risk/reward couplet in favor of crime prevention, it is possible to make it simultaneously easier to follow the law than to break it. Easy to understand income tax rules make it harder to justify continued, creative bookkeeping, on the one hand, and clearly fraudulent practices, on the other, as it becomes easier to be discovered by authorities and less likely you can explain it away as accidental or unintentional. Reducing provocation/temptation to commit an offense is a less intrusive method in achieving crime reduction or prevention. Together, these five objectives involve disrupting the scripts or crime templates that feed back into repeated criminal behaviors. How these concepts are thought to operate can be broken down into involvement and readiness categories of decision making.

Involvement Decisions

Although some people end up becoming offenders as a result of a snap decision, or so-called crimes of passion, most offenses do not result from such situations. Instead, nearly all offenders have made a series of decisions previous to the offense that, in effect, pave the way for criminal involvement during the long run. Debates occur regarding the speed with which this propensity to crime takes place, but the more important issue at hand for RCT is that some people are more ready (predisposed) to commit offenses than others. As has been shown above, this proclivity for rule violation stems from first entertaining the idea of breaking the law, examining the successes/failures of others, trying the behavior, and then readjusting one's expectations from one's own experiences and

those conveyed by others. By observing what works and does not work about criminal involvement, the evidence begins to mount as to whether it is time to become actively involved in crime, to continue to commit more crime when the opportunities present, or if it seems to be best to slow down such involvements or desist completely. Such learning and interaction with peer groups—and adapting some strategies but not others—shares common ground with the Chicago School but, again, without the degree of focus on “who” or especially “why” some chose to commit offenses, instead on the “what, when and where” questions. Offenders, according to RCT, are aware that they are contemplating criminal behavior and are prepared to act on this readiness when the situation is to their advantage to do so.

Event Readiness

Involvement decisions cover the long range, strategic planning of individuals as they build (or find) their respective moral compasses. At a more interesting level for crime prevention, however, is the more situationally specific decision of whether to commit a crime, right here, right now. This layer of decision making is much more conscious and overtly rational than the manner in which individuals acquire long-term predispositions to rule breaking. Readiness decisions are made within a short time horizon and, as one might expect, with patently incomplete information. Nevertheless, this is the situation facing offenders as they decide to move beyond a state of readiness and actually make it happen. People may not decide, in a literal sense, to drive while intoxicated when they set out for an evening’s entertainment at a night club or bar; however, it is the case that they put themselves into a situation where it is a possibility. If steps are not taken to avoid driving while intoxicated (such as making arrangements for transport via a designated driver), if that person chooses to drive home anyway, he or she has at a minimum decided that it is OK to commit this offense. More controversially, when a person decides to experiment with crack cocaine, or heroin, for example, one is unlikely to do so with the rational intent of becoming addicted. Yet a series of decisions is made that make it acceptable that one would be in a position to experiment with such substances.

Bounded (Limited) Rationality

Both involvement and event readiness decisions are made with the best available information and understandings of past experiences. Notice, however, that this does not demand that the information upon which individuals base their decisions be accurate, or that the logic with which they are applied be valid or effective for a given objective. A range of factors can impede the rational calculus beyond simple errors of logical reasoning, or misreading of the event-specific cues regarding the risk-reward determination. The most obvious is incomplete information. Crime opportunities that are discovered as a result of happenstance may lead a potential offender to overestimate the likelihood of a successful, spur-of-the-moment theft. Police sting operations take advantage of this line of reasoning in particular. In some jurisdictions, police use “bait cars” to capture would-be car thieves in the act—and on film, as many such vehicles are fitted with wireless microphones and cameras. Even those offenders who have diminished rational capacity as a result of drugs, alcohol, or mental disorders still make active decisions about when, and when not, to commit crime.

Criticisms

Criticisms of RCT start with its conception of rationality and argue that offenders are not nearly as cogent as described by its adherents. Crimes of passion, such as those resulting from a violent altercation between a couple that started as a result of an argument regarding household finances is an example. Still other criticisms argue that RCT misses several important structural (macro-level) variables that are commonly studied in crime, delinquency, and deviance research—gender, race, and socioeconomic inequality. Others find that RCT is too focused on preventing so-called street crimes, while ignoring root causes to crime generally.

Regardless of one’s preferences for how to study crime, or what one’s objectives ought to be, RCT provides a template for how it is possible to understand how crime happens, at a micro-level, by drawing our attention to the role of decision making in environmentally specific contexts.

REASSURANCE POLICING

Reassurance policing (RP) is a comparatively new perspective in the community policing tradition. It focuses on targeting those crime and disorder incidents that influence and “drive” public perceptions of rising crime and fear of victimization and, thus, experiences of insecurity. Although previous police strategies have prioritized crime reduction and prevention, RP focuses on the impact that crime and disorder have on levels of neighborhood security. This entry explores the emergence of RP, its practical implications, and how this approach addresses problems of crime and disorder.

Crime, Reassurance, and Police Strategy

From the 1970s until the mid-1990s in the United Kingdom, national crime statistics indicated that the level of crime was rising. During this period, policing strategies, such as zero-tolerance policing and intelligence-led policing, tended to focus on the objective of preventing and detecting crime. In the mid-1990s, however, along with several other jurisdictions, crime levels in the United Kingdom started

to fall and have continued to remain comparatively low. Nevertheless, reports from the British Crime Survey suggest that around two thirds of the public actually believe that crime is getting worse. This lack of correlation between recorded crime levels and public perception was concerning to policy makers and was something that several chief police officers began to refer to as the “reassurance gap” around 2001. They argued that the ability to narrow this gap required a change in the trajectory of development of policing policy and practice, and consequently, they suggested a need for a renewed interest in the notion of community policing. It is set against this backdrop that the concepts associated with RP emerged.

What Is Reassurance Policing?

In October 2003, the Police Standards Unit of the Home Office and the Association of Chief Police Officers launched the National Reassurance Policing Programme (NRPP). The idea of the NRPP was to design and test the capacity of a systematic approach to the local delivery of policing services to reduce both objective and subjective levels of neighborhood insecurity, while increasing levels of trust and confidence in the police. The approach that was designed and tested was built around three interlocking components:

1. Police officers need to be visible, accessible, familiar, and effective at a very local level.
2. They should target the signal crimes and signal disorders in every neighborhood that has the biggest influence on public perceptions of security.
3. Police staff should aim to coproduce solutions to the signal problems by working closely with communities and other local agencies, as this is likely to increase sustainability.

These components effectively integrate and synthesize the benefits that have resulted from other previous policing reform strategies, such as problem-oriented policing and intelligence-led policing. What was distinctively new was the emphasis on tackling “signal events.” By targeting resources and assets upon those incidents that act as signals of risk to communities, RP identified a rationale

for ensuring that policing interventions were precisely focused on the needs of individual communities and neighborhoods. This required a systematic and structured approach to community engagement in order to collect community intelligence on what really mattered to people, as opposed to relying on national performance indicators to determine policing priorities. Although an emphasis on the importance of the police engaging with communities adheres to most previous formulations of community policing, RP considerably extends and develops this. The community intelligence that is derived from engagement processes is the basic material that is used to analyze what issues are priorities for a particular community. As such, RP fundamentally aims to move the power of control back to communities so that individuals have a direct influence on how they are policed and policing is tailored to these needs.

An important element of the research that underpins RP theory is that it recognizes that public insecurities are not just determined by crime alone. In some areas, crime is an important determinant of neighborhood insecurity, but in other areas, antisocial behavior and physical disorders will be more influential. Thus, RP does not seek to distinguish between the relative importance of crime and disorder. Rather it suggests that in most areas both need to be tackled effectively and proportionately in order to manage neighborhood security.

Wider Influence

In contrast to most other policing perspectives that focus primarily on crime reduction, RP extends the remit of the police, arguing that they need to be directly concerned with subcriminal behaviors and public perceptions. In so doing, RP has been the key influence both conceptually and practically on several recent police reforms, most notably the national rollout of neighborhood policing across the United Kingdom. The evaluation of the NRPP demonstrated that a systematic approach to the delivery of local policing services, conducted in a manner precisely attuned to community needs, can impact on how safe people are (in terms of their likelihood of being a victim of crime) as well as on how safe they perceive themselves to be. This is because the problems that evoke fears among a particular community may not reflect the issues

deemed fearful from a police or government perspective. As such, the ability to reassure the public must include understanding the problems within and across communities, together with the individual and collective effects these incidents of crime and disorder have. That RP has achieved such an influence on the direction of police reform reflects a sense shared by several commentators and policy makers that insecurity and fear of crime are key social problems of the contemporary era.

REDUCING BURGLARY INITIATIVE

In 1999, the British government committed more than £250 million to the Crime Reduction Programme (CRP), to be administered by the Home Office in England and Wales. After the British government's 1998 Comprehensive Spending Review (CSR), the CRP was launched as an initiative in evidence-based policy—with the specific intentions both of grounding crime prevention in reliable knowledge about what works and of learning lessons from practical crime prevention activities—especially about cost-effectiveness—so that they might be passed on to future government programs and local crime prevention partnerships. A major component was to be the *Reducing Burglary Initiative* (RBI). This entry examines the RBI's history, implementation, and issues of evaluation.

History

The then–Home Secretary (Rt. Hon. Jack Straw, MP) commended the RBI to Parliament specifically as an evidence-based initiative. The CRP itself was justified to Parliament (in July 1998) with reference to the Home Office report *Reducing Offending*—a review of research enquiring into what works in the reduction of crime. The review aimed specifically to reverse what the British government perceived to have been the prevailing message taken from previous research (i.e., that “nothing worked” in the reduction of offending). Minister’s confidence was expressed in their wide-reaching *Crime Reduction Strategy*, but they were also encouraged by the claims of in-house Home Office crime prevention research and development. Two particular features of this research and development program were influential: first, an emphasis on “situational” methods of crime prevention, especially the application of techniques in ways that might enhance the efficacy of the police, such as problem-oriented policing; and second, an approach that is oriented specifically toward practice.

Nevertheless, the RBI was also the progeny of the British government’s 1998 CSR. In essence, the CSR is a mechanism for reallocating resources among the various spending programs of the government, the governance of which lies with HM Treasury. Equally part of evidence-based policy making, HM Treasury management of the CSR required spending departments to put forward analyzed evidence in respect of their proposals—including the Home Office CRP—and, importantly, in return for its investment, expected them to account for the cost-effectiveness of their resulting programs, using rigorously analyzed evidence, assembled according to its own guidelines. The HM Treasury required the CRP to be subject to rigorous, independent evaluation of its cost-effectiveness. Thus, the evaluation of the RBI was from the outset likely to become a hostage to these two contending definitions of evidence-based policy making: on the one hand, Home Office interest in the validation of utilizable techniques to reduce crime; and on the other hand, HM Treasury’s concern to establish that “what works is what counts” in the expenditure of public money.

Sixty-odd local *Strategic Development Projects* (SDPs) comprised the first phase of the Burglary Reduction Initiative and were subject to the most rigorous evaluation. Local Crime and Disorder Reduction Partnerships (CDRP; established by the Crime and Disorder Act, 1998) were invited to bid for funding as SDPs. They were asked to identify areas comprising 3,000 to 5,000 households that had experienced at least twice the national recorded domestic burglary rate during the previous 3 years. A successful number of bids to become SDPs subsequently worked with Home Office consultants to develop detailed implementation plans. These plans resulted in several different kinds of proposed measures, targeted at different aspects of each local burglary problem. In the end, around £60,000 (at 1999 prices) was granted by the Home Office to support each of these plans, although many SDPs also planned to “lever-in” additional resources (usually staff) from partner agencies in support of their range of measures.

The political tension produced by these countervailing definitions of evidence-based policy led to pressure being placed on the independent evaluation. This pressure resulted in the premature publication of results by the Home Office and in reliance on an inadequate and unreliable methodology for the assessment of cost-effectiveness. These methodological errors tended to bias the results toward Conclusion Error—accepting the results to be true when they might not be.

This entry is based on an evaluation of 21 SDPs undertaken by Tim Hope and his associates, who sought to avoid many of the potential errors, biases, and distortions that may have occurred in the other reports.

Project Implementation and Outcome

Several aspects of the SDPs were anticipated to bring about successful outcomes.

Strategic Planning

According to the Home Office’s consultants, the methodology of implementation was thought to comprise the identification and analysis of the burglary problem, the devising of solutions, an assessment of the likely impact of these solutions, a review of progress, the refinement of approaches, and the evaluation of success.

The results of the evaluation of the impact of the 21 SDPs on the 20 target areas found that there were three groups of projects:

- *Group A* ($n = 6$)—projects that brought about a statistically significant reduction in burglary in their target area over and above the local burglary trend.
- *Group B* ($n = 7$)—projects that brought about a reduction in burglary in their target area, although this was not significantly different from the local burglary trend.
- *Group C* ($n = 7$)—projects that seemed to bring about an increase in burglary in the target area, although only one of these was statistically significantly different from the local trend.

The chances of success of a project seemed to be enhanced if targets and objectives were set in the light of local burglary patterns and trends—what was referred to by the Home Office as the “local chemistry of burglary.” However, this chemistry would seem to be much more complex—and its dynamics more difficult to understand—than had been anticipated. In some circumstances, there may have been a favorable “virtuous” spiral of burglary reduction already occurring in the community, and there was also the possibility of inadvertently upsetting such trends and making matters worse. The problem for crime reduction projects was therefore knowing when, or even if, to intervene, and when to support what might be called the “natural” crime reduction activities that were going on within the community, that is, those that have little directly to do with the crime prevention project. Not many projects were able to do this, not because the evaluators’ denied them the information they needed but because of an absence both of a theory about local crime trends and a methodology to analyze them reliably. More sophisticated analysis of local crime trends and patterns would seem to be needed, similar to that used in Hope and associates’ evaluation research.

Packages of Measures

Projects were encouraged to include a mixture of “tried and tested” and innovative tactics. The developers encouraged the projects to remove contradictions and improve the mixture of measures

to ensure a systematic approach that would have a good chance of maximizing effectiveness.

The more successful projects comprised integrated packages of measures in two senses:

- Projects were not isolated either from crime trends or from other crime reduction and area-regeneration programs occurring in the wider area. Although several projects seemed to have a greater impact on their surrounding areas than in their own target areas, this can be perceived as a consequence of a wider set of activities, of which the projects were part, rather than a “diffusion of benefit” from their specific burglary-reduction efforts.
- Interventions that mutually supported and reinforced each other seemed more successful. This was especially noticeable for projects that reinforced their delivery of security and target-hardening with publicity and other “stakeholder-engagement” programs that sought to actively involve community residents, thereby reinforcing their own private security activities.

Crime Prevention Measures

Specific prevention measures were devised by the local projects, with assistance from the developers. Subsequently, these were classified into the following generic categories:

Areawide Situational Crime Prevention (SCP)—including alley-gating, environmental improvements, and closed-circuit television (CCTV) schemes

Enforcement—including gathering, analyzing, and using intelligence, disrupting offending behavior, high-visibility policing, and witness protection

Location-Specific SCP—including the surveillance and target hardening of individual dwellings

Tackling Offender Behavior—including youth diversion and drug abuse prevention and treatment schemes

Property—primarily property-marking schemes

Stake-Holding—including education, public awareness and publicity campaigns, and resident involvement schemes

A significant investment in SCP measures delivered to the community was more likely to be part

of successful projects than either enforcement or tackling offender behavior. In terms of expenditure, certain types of interventions seemed more likely to be associated with unsuccessful projects. A greater proportion of the least (Group C) and less successful (Group B) projects' expenditures went toward police enforcement activities—including “gathering, analyzing, and using intelligence”; “disrupting offending behavior”; and “high-visibility policing”—apparently to little avail. Similarly, a higher proportion of expenditure in these projects was devoted to measures intended to tackle offending behavior, and they spent the least resources on “stake-holding” projects to engage the local community, including education, publicity, and awareness schemes. This suggests that, in the short run, the activities of local offenders are most likely to be addressed indirectly via an increase in the level of private security among their potential victims in the community rather than through direct contact with them by public agencies.

Crime Prevention Tactics

There were also different tactics for applying these measures to ensure maximum cost-effectiveness, particularly a contrast between a *targeted approach*—based on the idea of identifying at-risk or vulnerable domestic burglary targets—and a *coverage approach*—where all possible targets are covered so that no one remains vulnerable.

The most popular targeted-approach was a strategy of reducing repeat victimization (RV). Seventeen out of the twenty SDPs proposed some form of repeat victimization prevention strategy as part of their agreed plans. Eight projects were proposed solely to target new burglary victims shortly after they had been victimized, whereas nine projects were proposed to add targeting components, such as targeting already repeat victims, “cocooning” nearby neighbors of recent victims, and targeting other vulnerable groups, for example, elderly households. Two major flaws with this strategy emerged across the projects. First, where changes in the rate of RV could be measured, there were no projects where it reduced—and some where it actually increased, even in situations where projects achieved a significant reduction in the overall burglary rate. Second, it emerged that part of the

reason for this was that the plans for RV prevention proposed by the projects—which were consistent with Home Office advice and had been approved by the expert project developers—faced considerable practical difficulties when implementation was attempted, to the extent that several, although not all, abandoned or considerably modified their targeting strategy. The main reasons for why this occurred are as follows:

- Too few victims/repeat victims resident in the target area.
- Some projects had persistent problems associated with the system of referrals of eligible cases from the crime-reporting and investigation process and/or delivery of prevention (usually some kind of target-hardening) to the identified target dwelling.
- Several projects faced low take-up among eligible victims, and high rates of refusals and noncompliance with the prevention offered them, often much to the surprise of the projects themselves. A variety of reasons exist for this, including an evident preference on the part of victims for self-help, linked to suspicion of the project's motives or personnel, victims' inability or refusal to contribute a share to the costs of the installation, and particularly in the case of households in multiple occupations, an inability to locate or ensure the compliance of the property owner.

Action Planning

If success for the projects would come about through strategic and tactical planning, then the more effort that was put in advance into devising strategies and subsequent action plans, the more confident were the Home Office consultants that success could be attained. Yet this conflicts with the aim of innovation: Because effectiveness depends, first and foremost, on successful implementation, approaches with a lower or known risk of failure during implementation ended up as more effective than more “radical” approaches that contained a greater or unanticipated risk of failure.

Generally, many planned interventions were never fully implemented with only about 58% of the total number of planned interventions (116) using more than 5% of their project's total

resources. Although the more successful projects (Group A) planned *fewer* interventions, they implemented proportionately *more* of them than the least successful projects (Group C). It seemed that the “smarter” projects chose approaches with which they were familiar rather than the more innovative approaches, although, of course, these also needed to have some promise of success rather than (1) merely being consistent with general agency practice or (2) innovative ideas from central government (such as RV reduction) that proved not to be particularly practical or effective (see the “Crime Prevention Tactics” section above).

Problem Solving

There were also two views as to what kind of problem solving would be needed. On the one hand, there is the view that problems are best solved by being anticipated and taken care of in advance, primarily through detailed action planning. On the other hand, it may be that the range, diversity, and complexity of practical and operational problems that might emerge during implementation cannot be anticipated easily and that solutions are more likely to develop from the practical and immediate experience of overcoming problems at first hand—an approach that sees implementation as a complex process of change, adjustment, and continuing innovation.

Although much attention has been given to problem solving as a method of working out what to do about specific, local crime problems, generally much less attention has been paid to taking a problem-solving approach to implementation. The more successful projects were also those that were able to take remedial action swiftly and soon when proposed interventions began to experience difficulties in practice. It was revealing what happened when they encountered implementation difficulties with their RV strategies. The more successful projects (Group A) were more likely to have abandoned or seriously modified their RV plans—usually to widen coverage or eligibility to other vulnerable groups or to residents generally. In contrast, the least successful projects (Group C) were much more likely to have persisted in seeking to implement their RV plans despite evidence that they were encountering difficulties. Since four of the six projects that persisted with their RV strategies

ended up seemingly bringing about an increase in burglary by their activities, it is difficult with this evidence to avoid the conclusion not only that their RV prevention tactics were ineffectual but also that persisting with them was misguided. Thus, the smarter and more successful projects were those that had the wisdom and/or resolve to look for alternative solutions to emergent implementation problems rather than to persist with their original plans.

Managing Delivery

Bids for the RBI were made by the multiagency CDRPs. Three levels of organization of the SDPs are likely:

Steering level—the level at which strategic planning would take place.

Management level—this would be where day-to-day project management would be carried out, responsible for action planning, including detailed targeting, specification, and negotiation with relevant stakeholders to the respective prevention measures.

Implementation level—this is the level at which the various prevention measures would be delivered to the community.

It seemed implicit in the planning of the RBI that the multiagency method of working would be appropriate and unproblematic at all levels of activity—not only for strategic decision making but also for management and delivery.

Although all projects were genuine partnerships, and all exemplified the new relationships embodied in the local CDRPs, the most successful projects had an organizational structure that used partner agencies differentially in ways that were fit-for-purpose. Although it may be best at the strategic level to maximize the number of partners involved to maximize local support and commitment, fewer agencies, with clear lines of responsibility and established procedures, are needed at executive and implementation levels. Since most projects more often resembled urban regeneration and environmental improvement programs, it is perhaps not surprising that the most successful projects were coordinated and implemented by partnerships between local authorities and regeneration contractors—agencies

with some expertise in this kind of work—in comparison with those that directly involved the police in day-to-day project management.

Projects with fewer partners, especially those led by the police, were generally the least successful largely because the police view of crime prevention tended to predominate. Police are more likely to favor enforcement—usually human resource-intensive (and, therefore, costly) police operations—that proved relatively ineffectual in burglary reduction. But neither did police managers seem to have the capacity or readiness to change or modify plans if they were proving ineffective. Partly, this is because of the police occupational culture—still more used to following standard operating procedures than problem solving. Additionally, since the police were tied into Home Office performance-driven accounting regimes that emphasized intelligence policing and RV prevention strategies, there may have been some reluctance among police personnel running the projects to question or abandon these measures in the face of difficulty. Since these particular performance criteria do not bear on local authorities, the latter personnel may have been under less constraint to demonstrate their performance in these particular ways and, thus, freer to pursue approaches that proved, in the end, to be somewhat more effective in reducing local burglary.

REINTEGRATIVE SHAMING

In 1989, John Braithwaite published his influential book, *Crime, Shame and Reintegration*. In it he canvassed his theory of reintegrative shaming. Reintegrative shaming theory has been posited as

being a general theory of crime because it synthesizes the predictions of several theoretical perspectives of criminal behavior into a single framework. Its most distinctive contribution is to focus attention on the effect of “shaming,” with shaming conceived of as encompassing all forms of social disapproval. The theory argues that the importance of social disapproval has previously been underestimated by Western criminal justice institutions, as well as by criminological theory more generally. Reintegrative shaming theory is premised on the idea that justice interventions will be most effective at reducing reoffending when they communicate disapproval of offending in a way that reintegrates an offender back into a law-abiding community.

This entry presents a brief summary of reintegrative shaming theory (both the original theory and its revised form) and a discussion of the role that shaming and shame play in predicting crime. Reintegrative shaming theory is both relevant and important to the subject of this encyclopedia because it provides an alternative way of thinking about crime control, which in turn has implications for reducing the level of victimization experienced in the community.

Reintegrative Shaming Theory Thesis

Reintegrative shaming theory attempts to give an account both of why some kinds of individuals and some kinds of societies exhibit more crime. Reintegrative shaming theory suggests that the key to crime control is a societal commitment to shaming offenders in a reintegrative manner. Braithwaite has demonstrated that societies with low crime rates are those who do not tolerate crime and who shame offenders potently and judiciously. His theory suggests that those who commit crime are those who are insulated from shame regarding their wrongdoing. At the same time, the theory suggests that shame can be applied injudiciously and counterproductively. The theory seeks to specify the types of shaming that cause rather than prevent crime.

Shaming is conceived by the theory to encompass all forms of social disapproval, which are intended to invoke feelings of shame and remorse in the person being shamed. Hence, by using the term *shaming*, as opposed to *disapproval*, it signals

an expectation that disapproval will result in a shame-related emotion. The conception of shaming provided by the theory has been left distinctly broad, such that shaming is not necessarily public or humiliating in nature. It can be subtle, such as a frown, a slight shaking of the head, or a snide comment. It can be a direct verbal confrontation where offenders are told how guilty they should feel and how their inappropriate act may have had a detrimental impact on others. It can be indirect confrontation by gossip, which gets back to the offender, or it can be broadcast through the media to a mass audience, or by a private medium through slogans spray-painted onto an offender's house. It can also be officially pronounced by a judge in the course of a sentence handed down by the court.

The theory's primary argument is that the communication of shaming (i.e., disapproval) is of central importance to understanding the effect that criminal justice actions have on the subsequent offending behavior of individuals. Two forms of shaming that occur in response to offending can be distinguished: (1) shaming that is reintegrative in nature and (2) shaming that is stigmatic in nature.

Shaming that is reintegrative in nature is carried out in a respectful and healing manner. Here, disapproval of an *act* is communicated with respect, and special effort is given to avert labeling the offender as a bad person, and to terminate disapproval with rituals of forgiveness or reconciliation. Shaming criminal behavior is complemented by ongoing social rewarding of alternative behavior patterns. It is predicted that reintegrative forms of shaming will result in less reoffending. Conversely, shaming that is stigmatic involves communicating disapproval of a *person* with disrespect, where offenders are labeled with outcasting identities (e.g., thief, tax cheat, and rapist), and there are no rituals to terminate disapproval. Reintegrative shaming theory predicts that this latter type of shaming results in greater levels of reoffending.

Relationship Between Shaming and Offending

As noted, the theory of reintegrative shaming synthesizes the predictions of several theoretical perspectives into a single framework for explaining crime. These theoretical perspectives include labeling, subcultural, control, opportunity, deterrence, and learning theories. A major contribution of

reintegrative shaming theory is that it attempts to specify the conditions under which these older theories hold true.

It is proposed that when shaming is communicated in a stigmatizing fashion, this is where labeling theory has explanatory power. Once a person is stigmatized with a deviant label (e.g., thief), the theory proposes that a self-fulfilling prophecy unfolds as others respond to the offender as deviant. Stigmatization is thought to lead to a master status trait, whereby the offender comes to internalize their deviant identity over all other identities. The offender then experiences marginality and becomes attracted to subcultures that provide social support for deviance. Criminal subcultures supply a collective solution to the status problems being faced by people who have been stigmatized and outcast. In the subculture, stigmatizing shaming works to reinforce offending because it is the law-abiding citizens who are shamed; deviance becomes a way of life that is difficult to change and is rationalized as a defensible lifestyle within the deviant subculture. Opportunity theory is also integrated into the framework. Subculture formation is fostered by systematic blockage of legitimate opportunities for certain members of the community (e.g., offenders). For example, if an offender is systematically denied economic opportunities because of the stigma of their previous behavior, then criminal subcultures will form among similarly outcast members of the community.

Control theory can be considered on the reintegrative shaming side of the theory. Reintegrative shaming theory asserts that individuals are more susceptible to shaming by other individuals when they are in relationships of interdependency. When interdependency is high—for example, when people are strongly attached (a concept of control theory) to their parents, partners, schools, community, employers, and so on—shaming of wrongdoing will be more effective. Criminological research on deterrence has also influenced reintegrative shaming theory. Such research has shown that sanctions imposed by relatives, friends, or a personally relevant group have more effect on criminal behavior than sanctions imposed by a remote legal authority. It has been suggested that this occurs because repute in the eyes of close acquaintances matters more to people than the opinions or actions of criminal justice officials.

Braithwaite proposes that the entire theory of reintegrative shaming can be viewed as a social learning theory. It is a theory where people learn criminal identities in criminal subcultures and learn law-abiding identities in interdependent communities. Most critically, the unthinkableness of certain crimes is learned by the disapproval (i.e., shaming) that highly respected others communicate toward such crimes.

In sum, shaming is described as affecting offenders' subsequent propensity to reoffend because it acts as a deterrent and has moralizing qualities that build the offender's own sense of conscience. The theory suggests that shaming is an effective deterrent because it poses a threat to relationships that are valued. This is particularly so when the shaming comes from those to whom the offender is close. Furthermore, because reintegrative shaming communicates that certain behaviors are wrong, it builds internalized controls that such behavior should not be repeated in the future.

New Directions

Several emotion theorists have a theoretical perspective on why reintegrative forms of shaming should reduce crime. They believe it has more to do with the nature of shame as an emotion than with shaming, reintegration, and stigmatization as regulatory practices. In other words, reintegrative shaming results in lower reoffending, at least in part, because it is more likely to promote feelings of shame in an offender. According to this perspective, shame can also be a destructive emotion because it can lead one to attack others, attack self, avoid, or withdraw. All of these are responses that can promote crime. Hence, a critique of Braithwaite's earlier theory of reintegrative shaming was that it was just a theory of shaming, with the emotion of shame left undertheorized. In other words, its weakness was in its failure to concentrate on the emotion of shame that shaming practices are supposed to induce. Although Braithwaite clearly envisaged shaming leading to a shame-related response, which in turn influences criminal behavior, the implication of whether shame gets bypassed or acknowledged in the process received little attention in the original formulation of the theory. In response to the recognized weakness of the original theory, a revision of the theory was

undertaken in 2001 to elaborate on the role that shame-related emotions play in mediating the relationship between shaming and subsequent behavior.

In the revision of the theory, John and Valerie Braithwaite suggest that individuals respond to, or manage, shame differently, and that the way in which this shame emotion is managed has important implications for future behavior. A considerable research tradition shows that one way of managing shame is through acknowledgment of the emotion, and that this response is associated with empathy for victims, less anger, and less externalization of blame. Thus, it has been posited that reintegrative shaming results in lower offending, at least in part, because it is more likely to promote acknowledgment of shame by offenders. In contrast, it is argued that stigmatic shaming is less likely to elicit acknowledgment of shame, or a sense of remorse, in an offender because it serves to humiliate an individual. Here, individuals are more likely to bypass shame, whereby they externalize blame for what has happened and are more likely to direct anger toward the entity expressing disapproval, which is an emotional state that has been referred to as unacknowledged shame or shame displacement. Such feelings of hostility increase the probability of defiance and noncompliance exhibited by the offender in the future.

Empirical Support

Despite the popularity of reintegrative shaming theory in the field of criminology, and its importance to the practice of restorative justice, only a few empirical studies purporting to test its underlying assumptions have been published to date. Of the studies that have explicitly tested the predictions of reintegrative shaming theory, most have been conducted in the context of juvenile or blue-collar crime. Recent research has attempted to investigate reintegrative shaming theory in the white-collar crime context to see whether the theory offers a useful framework in which to explain white-collar offending. In general, these studies either support the hypothesized relationship between the shaming variables and noncompliance or find partial support for them. The research has also found supporting evidence for the mediating role that shame-related emotions play in the shaming/compliance relationship. Despite growing empirical support for the

theory, however, much more research is needed before firm conclusions regarding its validity as a general theory of crime can be made.

REPEAT VICTIMIZATION

Repeat victimization has both a narrow and a broad definition. The narrow definition refers to repeated offenses against the same person, household, business, or other target however defined. The broad definition refers to repeat offenses against targets with equivalent profiles such as nearby households, the same type of electronic products, or individuals with similar demographic or lifestyle characteristics.

Most violent and personal crime is repeat victimization. For all crime types covered by the

International Crime Victimization Survey (ICVS), more than 40% is repeated against the same targets in any given year—a conservative estimate. Repeat victimization has a heightened risk in the period immediately after victimization. Since society is more informed about where, when, and to an extent repeat crime is likely to occur, this means as members of society we really ought to be able to do something to prevent it. It is often not intuitively obvious what should be done or how, although sustainable measures will tackle both long- and short-term repeats. Developing crime prevention tactics to tackle repeats is sorely neglected, and most of the research remains to be done.

Offenders are creatures of habit, selecting the same or similar targets because they have learned the likely amounts of time, effort, skill, and resources they need, and the risks and rewards involved. Hence, success breeds repetition, although repeats can be driven by frustrated attempts. Particularly attractive targets may also draw crimes from different offenders. Some households or businesses may contain particularly valuable products, or some persons may seem particularly vulnerable and attractive. For example, targets of hate crimes who are visually distinguishable may be repeatedly victimized by different offenders with a shared motivation. Victims of personal crime are statistically more likely to also experience property crime, and some explanation is provided by lifestyle theory: People who frequently go out, to bars and clubs for example, may be at risk of alcohol-related violence and theft, while their homes are left unguarded against property crime. Routine activity and crime pattern theory provide the best explanation of aggregate patterns of repeats. The same targets go to the same places where they interact with the same offenders, whether on the streets, in the home, or online. This is as true for domestic violence (typically with one offender and victim who routinely interact), neighbor assaults (because of their proximity and frequent interaction), crimes that occur along the routes that victims and offenders take to and from work and leisure activities, and cybercrimes including fraud, identity theft, and hacking where the same targets are repeatedly victimized. Murder seems to be the only crime where repetition does not occur.

Research on repeat victimization emerged in the 1970s, not least because of methodological studies

relating to the National Crime Victimization Survey (NCVS). But the key catalyst was the Kirkholt Burglary Prevention Project in the mid-1980s. This was the first research to overtly develop the prevention of repeat victimization as a crime prevention strategy. Research, policy, and practice developed hand-in-hand during the next 15 years as told in Gloria Laycock's "Repeat victimisation story." Studies sponsored by the National Institute of Justice included testing problem-oriented policing approaches, further NCVS analysis by Jim Lynch and colleagues, and efforts to prevent repeated domestic violence.

Empowering victims with an aim of preventing repeat victimization means work has become integrated with that of victim services. It is better to tell victims the truth about heightened risk rather than to mislead by suggesting that lightning doesn't strike twice. For police and policy makers, preventing repeat victimization can bring efficiencies via the drip-feeding of resources to persons, places, and targets most in need. A range of good practice has evolved. Successful crime prevention efforts tend to be situational in nature, reducing opportunities for repeat crimes. They are characterized by a strong preventive mechanism and good implementation, although these are not necessarily easy to achieve. It is simply not yet clear how to intervene to prevent the recurrence of some crimes. And it is not always easy to motivate victims to take preventive action, particularly if expenditure is required and since future risks may still seem low.

Policy relating to victims and crime prevention is increasingly informed by research evidence, particularly surveys. Yet the key crime surveys, including the NCVS, ICVS, and the British Crime Survey (BCS), tend to omit much of the experience of repeat victims from national crime counts. They do this by limiting or excluding series crimes, which means that only the first few crimes that a victim experienced are counted. The practice undoubtedly originated out of good intention, probably when it was thought some victims were exaggerating or inaccurate, but it continues to this day. In the 1970s, it was thought the NCVS excluded around 20% of U.S. crime by ignoring frequent victims, but research in 2007 shows the exclusionary effect is far greater with both the NCVS and the BCS often excluding half or more of violent crime. This systematic and prolonged

distortion of national crime rates is likely to bias evidence-based policy away from the most vulnerable victims. This is particularly unfortunate because the effects of frequent victimization can be multiplicative rather than additive. Although it might be a little embarrassing for governments to begin to recognize frequent victimization, this is no excuse, and post hoc attempts to rationalize their exclusion remain unconvincing to many in the field of crime prevention and victimology.

There were few if any convincing explanations of the significant drops in crime experienced in most industrialized countries in the 1990s and 2000s. Katherine Thorpe's BCS analysis found multiple victimizations fell 51% in the decade to 2006, whereas single incidents fell only 16%.

Tackling crime concentrations by interrupting their repetitive nature should be known as a Pease Response to crime (after the director of the Kirkholt Burglary Prevention Project) and is an emerging area of research and practice. Repeat victimization occurs at the interface between repeat offending, geographical hot spots, and frequently stolen hot products. Preventing repeats may thus provide inroads into the trickiest concentrations of crime. As a key emerging area where victimology overlaps with crime prevention, most of the research on repeat victimization remains to be undertaken.

REPEAT VICTIMIZATION, THEORIES OF

Repeat victimization is important because most criminal events take place as some form of repetition. There are theories of the role of repeat victimization for policy and practice, and there are theories of why it occurs.

The narrow definition of repeat victimization is that it is the recurrence of crime against the same target. The broader definition now includes repetitive victimization across different dimensions. Spatial repetition produces *hot dots* and *hot spots* on maps. Repetition of target characteristics or *virtual repeats* results in frequently stolen *hot products* and places that are *risky facilities*. Most clusters of crime are types of repeat, including *sprees* (temporally focused by the same offender) and *series* (same offender, same target). Twelve types are shown in Table 1, and although they overlap (e.g., same offender and same modus operandi usually means the same crime type), the typology has heuristic value and illustrates a set of theories and concepts relating to repeat victimization.

Theories of Repeat Victimization for Policy and Practice

The most important theory of repeat victimization to date is that it can improve the efficiency and effectiveness of crime prevention practice. Offered

Table 1 Twelve types of repeat victimization

	<i>Target</i>	<i>Offender</i>	<i>Place/Location</i>
Spatial	Same residence, business, vehicle, or other target: <i>hot dots</i>	Same offender at same place	<i>Near repeats</i> (neighbors, etc.); <i>hot spots</i> ; <i>risky facilities</i>
Temporal	Quick repeat against same target	Quick repeat by same offender—can be a <i>spree</i>	Quick repeat not necessarily by same offender
Crime type	Same crime type against same target	Same offender, same crime type—a <i>series</i>	Same crime type in same place (e.g., drug dealing)
Tactical (modus operandi [m.o.])	<i>Virtual repeat</i> —same m.o. for target of same characteristics—produces <i>hot products</i>	Same offender, same m.o.	Same m.o. facilitated by same location (e.g., graffiti on white wall)

as a passing hypothesis in Michael Gottfredson's work, the theory was formally developed by Ken Pease following the Kirkholt Burglary Prevention Project, a 1980s demonstration project to prevent burglary in public housing. Repeat burglary was observed to be frequent, and Pease theorized that preventing repeats could prove an efficient strategy for crime prevention; limited resources are allocated to at-risk targets. In Kirkholt, repeat burglaries were prevented as part of a set of measures, and repeats were largely eliminated with overall burglary significantly reduced.

The Kirkholt work was a catalyst for additional studies. It was soon found that repeat victimization occurs for all crime types but with personal crimes generally proving more repetitive. Repeats were found to recur quickly, but the risk decayed over time. This led to theorizing that prevention resources should be put in place quickly to prevent repeats. More recent studies show that *near repeats* are more likely; that is, neighbors of those recently burgled are at more risk. The reason for near repeats is because it is a known area; the layout of the residence and expected household contents would be similar, but explanatory theories are discussed below. The near repeat is the spatially defined version of the *virtual repeat* wherein targets with the same or similar characteristics are victimized on that basis. So the same types of cars are victimized in similar locations, and the same type of consumer products are stolen because they

are attractive—linking repeat victimization to theories of hot products and product design.

It was theorized that the prevention of repeat victimization would be less likely to produce displacement than more general crime prevention efforts. This is because it would interrupt an offender's expected train of events or "script" and could be classed as a specific component of a general theory of familiarity decay (wherein offending is less likely as things get less familiar). Likewise, it was theorized that, since police respond to crime, then repeat victimization would be a useful performance indicator for policing, and it was introduced as a performance indicator in some areas. A summary of hypotheses relating to repeat victimization as a crime prevention strategy is given in Table 2.

With regard to other areas of policy and practice, it was theorized that the work of victim services would be more effective with a greater orientation toward repeat victimization. It is better, goes the theory, to provide victims with the unattractive truth (that repeat crime is more likely) rather than the untrue platitude that lightning does not strike twice. It was hypothesized that the provision of advice relating to, and assistance in preventing, repeat victimization, would empower victims.

Repeat victimization has also influenced methodology, that is, the theory of how research should be conducted and crime measured. It has been proposed that the extent and importance of repeat

Table 2 Theory and hypotheses on preventing repeat victimization

1. It is an efficient means of allocating, in time and space, scarce prevention resources to crime problems.
2. It is relevant to all crimes with a target. This includes hate crimes, domestic and commercial burglary, school crime (burglary and vandalism), bullying, sexual assault, car crime, neighbor disputes, credit card fraud, and other retail sector crime, terrorism, domestic violence, and child abuse. Even murder can be a repeat of attempted murder.
3. Prevention resources should be allocated according to the fact that the risk of repeat is highest in the immediate aftermath of a crime.
4. Repeats are more likely where the crime (e.g., a bank robbery) was successful.
5. It naturally allocates resources to high-crime areas, crime hot spots, and the most victimized targets.
6. It can allocate crime prevention to nearby targets (near repeats) and targets with similar characteristics (virtual repeats).
7. It is a practical form of “drip feeding” of prevention resources. Resources need only be allocated as victimizations occur from day to day.
8. It is less likely to result in displacement than unfocused crime prevention efforts.
9. It changes the crime situation so offenders are made uncertain and deterred. This is more likely to produce a positive domino effect such as a diffusion of crime control benefits.
10. It generates a positive domino effect from common goals and positive work between agencies (e.g., police, housing, social services, and victim organizations), which facilitates cooperation.
11. It empowers agencies to do something tangible and constructive to help crime victims.
12. It can lead to positive feedback from victims to agencies—still a relatively rarity—promoting good community relations.
13. It can sometimes—but not always—use off-the-shelf prevention tactics rather than requiring inventive and sometimes difficult problem solving.
14. It can enhance the detection of serious and prolific offenders.
15. It presents possibilities for preventing and detecting organized crime and terrorism.
16. It can inform thinking on repeat crimes typically perceived as “victimless” where the repeatedly victimized target is the state or nation.
17. Police managers, from the national to the local level, can use repeat victimization as a performance indicator.

victimization is such that all crime-related studies need to take it into account. The crime concentration rate (the number of crimes per target) has become the third measure of crime to complement the crime incidence rate (crimes per capita) and the prevalence rate (targets per capita). Repeat victimization has influenced statistical analysis. Specifically, the distribution of victimization in a population (exhibited as a long tail in a frequency distribution) is such that statistical method that does not account for this tail is less applicable. More recently, it has been shown that most key crime surveys significantly undercount crime by

excluding many crimes experienced by the chronically victimized.

Theories Explaining Repeat Victimization

Some repeat victimization would be expected by chance but in amounts trivial when compared with what is observed. There are two main explanatory theories of nonchance repeats:

1. *Flag theory.* Repeat victimization occurs with greater frequency against particularly attractive or vulnerable targets. This is the theory of *risk*

heterogeneity (unevenness of risk) or of the *flag theory* (victimization flags some targets as being risky).

2. *Boost theory*. Victimization leads to a greater likelihood of a repeat victimization. That is, victimization *boosts* the likelihood of repeat victimization, a theory also known as that of *event dependence* or *state dependence* (because the likelihood of one event or state depends on the previous event or state).

The theories are interrelated because a target must flag itself as attractive or vulnerable in order for a crime to occur that boosts the likelihood of another. Both theories are undergirded by routine activity theory and rational choice theory. It is “rational” to offend against a target that appears more attractive or vulnerable. It is “rational” to repeat the victimization of a target that is now known to be easy, entail little risk, and offer high rewards. Routine activity theory is implicit because repeat victimization makes it clear that offender decisions are influenced by characteristics (and therefore theories) of the target play as well as characteristics (and therefore theories) of the environment in which crime occurs.

Tests of Preventing Repeats

Empirical tests of the theory that preventing repeat victimization can prevent crime have been limited in scope and have produced mixed results. Most studies examine residential burglary with some focusing on commercial burglary, sexual victimization (particularly in the pioneering work of Christine Gidycz and her colleagues), and domestic violence, despite that repeat victimization has been shown many times to be widespread in terms of crime type and context. This overview relates to studies using the narrow definition of repeat victimization against the same target.

Efforts to prevent repeat victimization have stumbled at different stages. Some efforts have been located in areas where rates of repeat victimization were not high even before the project. This can occur when political factors determine where crime prevention resources are allocated. Weak preventive tactics are another problem. If the tactics have a weak preventive mechanism, then crime

will not be prevented. For example, education of victims of sexual assault may lead to changes in knowledge and attitude but not necessarily to changes in behavior or risk. Lack of implementation of tactics produces other problems. If good tactics are not implemented in sufficient quantity, then crime will not be prevented. For example, if advice is offered on security that would prevent crime but that security is not adopted, then nothing has been done to reduce the risk of repeat crime. Some projects provided funds for security or partial funds and incentives to promote implementation. In Deborah Wiesel and John Stedman’s research funded by the National Institute of Justice to prevent repeat burglary in Dallas, Baltimore, and San Diego, the police did not have funds to provide the security they recommended, so implementation rarely occurred, despite that this was one of the few projects to assess other measures taken by victims.

Other practical issues have been identified. Official police data of recorded crimes are notorious for underrecording repeat victimization. This makes it difficult to identify appropriate areas or targets, difficult to identify preventive responses, and difficult to know where to allocate resources. This measurement failure can be related to evaluation failure. Evaluation failure can occur if crime was prevented, but there are insufficient levels of repeat victimization to detect success in evaluation. It can also occur if crime was not prevented, but the evaluation is insufficiently informed to determine this with certainty.

Recent efforts at theory testing suggest that what works to prevent repeat victimization are as follows: a strong preventive mechanism, that is, a set of suitable preventive tactics, and good implementation, that is, ensuring the victim/target adopts the tactics. Several studies that have examined prevention efforts have also studied the effect on victims. Generally speaking, victims seem to prefer to know (when the alternative is to not know) that the risk of repeat crime is greater. They also seem to prefer a police response that seeks to give practical crime prevention advice rather than the platitudes that previously characterized the response to crime. However, since these have usually been a secondary component of research seeking to evaluate crime prevention impact, they cannot be stated with certainty.

From the value-based perspective that preventing crime is a good thing, efforts to prevent repeat victimization to date have been disappointing. It would seem relatively simple—in theory—to put something in place to prevent the “same” crime from occurring again. But things are proving more difficult in practice. However, with surprisingly few evaluated rigorous efforts to date, future efforts would need to build on this knowledge base to develop more informed responses.

Tests of Explanatory Theory

Qualitative interviews with offenders provide insight into how and why repeat victimization occurs. A burglar interviewed by Mike Sutton said he would go back repeatedly to the same shops because it was so easy and they had not done anything to stop him:

I've done some shops four or five times and all they've done is repaired the counter and replaced the window.... (Farrell and Pease, p. 125)

Another noted how he learns:

If I do a place and it's got good stuff in it—I think to myself “I'll come back two months later.” Guaranteed, y'know what I mean? If it's good I'll come back. I did this [victim] once three times before he got a [security] system up there—alarm bell. After I saw the alarm I thought “Aah, I'll leave it now.” (Farrell and Pease, p. 126)

These were examples of boost explanations. Yet there is also insight provided by explanations as to why repeat victimization does not always occur. Although many burglars repeat crimes against the same residences, some do not. One suggested he thought risk would increase, stating,

With a house they tend to have neighbors and they tend to say to the neighbors “I've been burgled—keep your eyes out” or they make sure that someone is in the house all the time. (Farrell and Pease, p. 126)

Other burglars observe rules such as “never go back” because they fear identification by neighbors.

Quantitative analyses of crime victim surveys have been a key tool for theory testing. Victims are sometimes asked whether they knew the offender(s) involved and/or whether they had reason to believe it was the same offender(s). With variation by crime type, around three quarters of repeat victimization is by the same offenders. This further suggests the explanatory importance of the boost theory of repeat victimization.

A major empirical finding that remains largely unexplained is the role of repeat victimization in the 1990s crime drop. Katharine Thorpe studied repeat victimization in England and Wales during the decade where, from the mid-1990s, the volume of many crime types fell by around half—in a fashion not dissimilar to the U.S. crime drops of the 1990s. The number of single-incident crimes fell 16%, but the number of repeat crimes fell 51%, concluding that the large decline in repeat victimization played a major role in the crime drop.

Final Thoughts

The study of repeat victimization has opened a rich vein of theory and hypothesis testing for victimology and crime prevention. Policy and practice theory has developed alongside etiological theory. Much work remains to be done if this research is to realize its potential for the alleviation of suffering.

REPRESSED/RECOVERED MEMORIES

In the early 1990s, courts across the United States saw an increase in the filing of civil and criminal cases by adults who alleged abuse, typically sexual, that had occurred when they were children. Likely the result of increased public attention to child abuse, new legislation that extended statutes of limitation in such cases, and improvements in mandatory reporting laws, victims alleged that they could not have filed their claims sooner because either they did not recall the abuse until adulthood or did not appreciate the causal relationship between long since ceased abuse and currently presenting injuries.

Often referred to as “repressed” or “recovered” memories, scientists also refer to the phenomenon of not being able to recall abusive events as “dissociation,” “traumatic amnesia,” and “dissociative amnesia,” among other things. Labels aside, the fact that the brain is able to avoid conscious recall of traumatic information has been recognized in medical literature for more than 100 years. Researchers who studied World War II veterans and survivors of the Holocaust, for example, found that many test subjects endured periods of time when they had no recall for the traumatic events they had experienced.

In the 1990s, when victims of child abuse described experiencing something similar, their claims were met with skepticism—primarily by advocates and expert witnesses working on behalf of offenders in civil and criminal litigation. Accused offenders even formed a support group called the False Memory Syndrome Foundation, although no such syndrome has ever been scientifically verified. This group was founded by the parents of a victim who alleged credible and corroborated allegations of abuse against her father.

Foundation members claimed that repressed/recovered memories had been implanted in their accusers and were the result of leading questions or suggestive therapy, although studies consistently show that it is virtually impossible to successfully implant a false memory of abuse. With the exception of extremely young children, research consistently reveals that people fiercely resist efforts to falsely convince them that they were abused.

Language used to discuss repressed/recovered memories has caused some confusion. “Repression” and “dissociation” are meant to express the theoretical ways in which the brain avoids conscious recall of traumatic events. Some people use the word “amnesia” to describe the experience of not remembering. The phrase “recovered memories” usually refers to the process of remembering something that was once unavailable to the conscious mind, and it is “recovered” as a result of a stimulus event such as smelling or hearing something, or seeing a movie or a photograph, that reminds the victim of the abuse. The most widely accepted term to describe the experience of “repression” is “dissociation,” and the most commonly held theory used to explain dissociation is that the brain cuts off, or separates out, experiences that are

emotionally overwhelming. In this way, the body avoids pain by storing the information in a manner that insulates the individual from psychological injury. And yet, in an aptly named study, Bessel van der Kolk notes in “The Body Keeps Score,” that traumatic experiences remain stored someplace in the body, usually manifesting in symptoms indicating extreme stress such as self-mutilation, eating disorders, anxiety, and sexual dysfunction.

When a victim remembers an event that was once unavailable to memory because of dissociation, questions can develop as to the authenticity of the information recalled. Although most studies find that such memories are no more likely to be incorrect than “ordinary” memories, some researchers claim that the process of recovering such information is highly vulnerable to distortion. One study purports to prove not only that recovered memories can be distorted but also that entirely false memories can be implanted. Titled “Lost in the Mall,” researchers claimed they were able to persuade 25% of test subjects to believe, falsely, they had been lost in a shopping mall as young children. The methodology behind this study has been heavily criticized, but even if the data were sound, courts have generally ruled that a study about whether people can be misled to believe they had once been lost in a mall has little bearing on whether a particular individual’s memories of child abuse are valid.

Researchers agree that it is exceedingly difficult to conduct research on the mind’s ability to repress or recall abusive events as this would require scientists to somehow cause test subjects to experience abuse so that their reactions could be studied. But it is noteworthy that researchers have tried, but failed, to make test subjects falsely recall receiving a rectal enema as a child.

When cases involving repressed/recovered memories of abuse are presented in litigation, the accused may seek to use an expert to testify that the victim’s memories are false or so unreliable as to be inadmissible in a court of law. The victim may also seek to use the skills of a different expert to testify that the experience of repression is not uncommon, and that the victim should not be denied justice when, through no fault of his or her own, the victim failed to remember the abuse and/or assert his or her rights sooner.

Although the law is still evolving, most states have recognized that repression/dissociation is an accepted medical and psychological phenomenon, and thus, victims are generally allowed access to justice even many years after the abuse has ended under the so-called delayed discovery rule. This rule provides that no person should be denied the right to seek legal redress based on the passage of time when the “discovery” of the abuse and related injuries could not have occurred earlier. Likewise, as testimony about false memory syndrome is widely perceived as unsupported by methodologically valid research, accused offenders and experts seeking to testify that a victim’s memories of abuse were implanted are usually forbidden to do so.

RESOLVING CONFLICT CREATIVELY PROGRAM

The Resolving Conflict Creatively Program (RCCP) is a universal (or primary) multiyear intervention program for preventing violence and creating caring communities of learning. The broad aim is to improve school success and safety for all children. The RCCP is one of the largest

and longest-running school programs focusing on conflict resolution and intergroup relations in the United States. It is one of a growing number of evidence-based programs that promote the positive impact of social and emotional learning in schools. It has been found that students who have strong social and emotional skills are better connected to the school community, which in turn acts as a protective factor against violence, substance abuse, emotional distress, and early sexual behavior.

RCCP objectives are to (1) reduce violence and violence-related behavior, (2) promote caring and cooperative behavior, (3) teach students life skills in conflict resolution and intercultural understanding, and (4) promote a positive climate for learning in the classroom and school. These objectives are operationalized through a classroom curriculum taught by teachers, who receive 25-hour introductory training and ongoing coaching from RCCP staff. Classroom skill development occurs through a series of age-appropriate workshops, including active listening, expressing feelings and dealing with anger, assertiveness, collaborative problem solving (including negotiation and mediation), appreciating diversity, and countering discrimination.

Administrators are brought on board early as they are key to establishing “discipline” as a vehicle that helps children learn to take responsibility for their actions and develop self-management skills. Administrator support is also a pragmatic necessity, as teachers need common planning and release time for professional development and implementation planning sessions. Workshops for parents are another important cornerstone of the whole school approach, where they learn and discuss the concepts of creative problem solving and conflict resolution, and practice the same skills and strategies their children are learning in school. Thus, all members of the school community (administrators, teachers, students, and parents) learn, model, and practice a common skill base to strengthen relationships.

The RCCP began in 1985 as a collaboration between the New York City Public Schools and a New York chapter of a nonprofit organization, Educators for Social Responsibility. A National Center was established in 1993 to develop multiyear partnerships with school districts to support RCCP dissemination efforts throughout the United

States. A range of school districts were involved in the initial evaluations of the RCCP, including Anchorage, Alaska (1999); Atlanta, Georgia (1997); New York, New York (1997); and Lincoln County, Oregon (1997–2000).

Anchorage, Alaska, surveyed teachers and students from 36 public schools. The findings showed that the level of RCCP implementation correlates positively with common use of conflict management language; sense of community among staff; articulation of feeling and understanding of conflict triggers; and academic achievement for students. This evaluation suggests that fostering RCCP characteristics through including these elements in classroom instruction on a consistent and regular basis promotes the emotional, social, and ethical development of students while fostering a caring and cooperative learning environment.

New York City surveyed students from 15 elementary schools. This study found that regardless of gender, grade, or risk status children who receive an average of 25 RCCP classroom lessons reported significantly slower growth rates in hostile attributions, aggressive fantasies, aggressive problem-solving strategies, and teacher-reported aggressive behavior. For this same group of children, teachers reported increased positive social behaviors and emotional control and greater improvement on standardized academic achievement. The research further suggests that each year a student participates in the RCCP has an additive effect on slowing rates of many of the risk factors for aggression and violence.

Atlanta, Georgia, surveyed teachers, parents, and students. This study found that teachers reported less violence in their classrooms (64%) and an increase in student cooperation (75%). Students reported feeling better about themselves (92%); parents reported an increase in their own communication and problem-solving skills (90%). Suspension rates at the middle school decreased significantly compared with the increasing rate among middle schools without the RCCP. Dropout rates at the RCCP high school decreased significantly compared with the increasing rate among non-RCCP high schools. Student and teacher attendance improved in RCCP schools.

Lincoln County, Oregon, surveyed teachers, parents, and students from 15 schools. Teachers reported their preparation for implementing the

RCCP was effective in increasing knowledge and understanding of conflict resolution principles; preparing them to infuse RCCP principles and practices into their regular curriculum and classroom management strategies; and providing appropriate demonstration lessons that could be used in the classroom with students. The majority of teachers reported they used conflict resolution principles and materials at least once per week; taught lessons on conflict resolution, feelings, cooperation, peace, communication, and affirmation (district-identified priorities); and taught curriculum units on diversity in the classroom. Students reported that they used the conflict resolution strategies to some extent and those who engaged in conflict resolution behaviors felt good about themselves, cooperated with others, and cared about what other people felt. Parents reported that their children used the conflict resolution behaviors to a high or medium extent. The impact of the RCCP on students included the following: fewer stayed home from school because they felt unsafe (compared with middle-school students statewide); fewer felt likely to carry weapons to school; they were less likely to be involved in a physical fight at school or off school grounds; they were less afraid of being beaten up on their way to or from school; they were less likely to be robbed or to witness students stealing; and they were less likely to be pushed by someone just being mean. Overall, students reported their environments were better in terms of safety, racial diversity, and staff respect of students' views.

Youth violence and safety is an ongoing concern. In response, two out of three schools now use a violence prevention program. The evidence base of the RCCP shows that it targets factors that lead to violence, as well as reduces the precursors of aggressive and violent behavior.

RESTITUTION

In the context of victimology, restitution is an important alternative to deterrence, rehabilitation, and retribution. Although the two former focus on the criminal, and the latter focuses on reinforcing the legitimacy of the criminal justice system by, possibly, affording the victim with some sense of "closure," restitution focuses on the victim's loss and offers insights, means, and techniques for mitigating or minimizing the physical, psychological, and social impacts that are experienced personally by people as victims. In fact, restitution addresses the problem of victim suffering along many dimensions and on several levels. Along the conceptual dimension, for example, it changes the way we conceive of crime, punishment, and the criminal with what many consider a more sufficient respect for victims. On the macro-level, it suggests changes in the design, practice, and procedure of our criminal justice system; changes that take the victim's situation into account more fully. And on the micro-level, it suggests changes in the way we might treat victims empathically after a criminal experience. This entry defines restitution as understood in the Anglo-American legal tradition, provides some historical perspective on restitution, presents some of the core issues surrounding restitution as an alternative response to crime, and in its course it supplies a brief consideration of the conceptual, macro-level, and micro-level changes that it implies.

Definitions

It just makes sense to many, given that people are responsible agents and that the state has taken the role of public guardian, that those among us who break our laws knowingly and intelligently should be required to work in order to pay for the damage that they cause; and if the wrongdoer is truly incapable of working, then it seems equally sensible that their victims, at least, should be compensated by way of public funds accumulated through the

collection of fines. The term *restitution* was invented as a shorthand for this common sense approach to crime and the criminal, but as legal scholars exalt in ever more refined particulars, three terms are now required by way of clarification. Hence, *reparation* is generally employed as an inclusive term, with *restitution* and *compensation* being reserved for the different forms that reparation may take. *Compensation* is generally employed when talking about reparation for damages to property or injury to persons, and *restitution* when talking about forms of redress that must be added to compensation in order to restore the financial and physical status quo ante, so far as that is humanly possible, and to mitigate the consequences of the wrong including psychological harm. All three terms are most popularly restricted to characterizing monetary forms of amelioration, although there are a few who would extend *reparation* to include deliberate attempts to rehabilitate wrongdoers socially with an eye toward restoring social harmony.

The extent to which this common sense definition reorients our understanding of crime and the criminal should not be underestimated. Crime, for example, is reconceptualized as any act that intentionally and maliciously does serious harm to a person or their property, as opposed to a statutory prohibition presenting it as an affront to the state or an act that does violence to an ideal vision of how people should behave. Perhaps this is a subtle distinction, but it is meaningful nevertheless as it forefronts the principle that governments exist, first and foremost, to secure the blessings of liberty to ourselves and our posterity. Also, by making it most clear that crimes in actual practice are personal afflictions visited by one person upon another, directly or indirectly through their property, it reminds us that there are at least two *people* involved, a wrongdoer and the injured rather than an evildoer and the state. This realization inclines us toward prioritizing remedies over chastisements. And this inclination leads us, as well, to consider the possibility of resocializing wrongdoers, although some may not respond, rather than treating them necessarily as rebels, heretics, and things to flout.

History

For a considerable period of time, death or restitution were the preferred responses to crime as

evinced by the Code of Hammurabi, the Torah, the Sumerian Code, and Roman law, each borrowing from the historically previous code rather liberally. Offenders unable to pay were banished. Upon the Roman Empire's demise, the Angles, Saxons, and Jutes invaded the British Isles, replacing Roman criminal law with their tribal customs, chiefly the "blood feud," a custom of exacting revenge for a perceived wrong in an eye-for-an-eye fashion upon the offender or any of the offender's kin. Intriguing, though, was the parallel option of satisfying the wrong by paying compensation to the victim or the victim's family, presumably prior to consummation of the blood feud alternative. Frankish law, for example, contemplated payments for theft, rape, arson, assault, and murder.

In time, the option of payment gained sufficient purchase, although glacially, to displace the blood feud as the favored custom. By the 7th century, for example, a series of laws, called "dooms," began prescribing monetary fines for different kinds of criminal wrongdoing. By the 9th century, victims and their families were habituated to seeking redress from royal officials by way of these dooms, and by the 11th century, the blood feud all but vanished as a remedy for criminal offense on the British Isles.

Then, in the 11th century, William the Conqueror swore, after subjugating all of England, that as king he would maintain the Church of God and all Christian people in true peace by prohibiting all orders of men from committing injustice and oppression. Thereafter, enjoining the observance of equity and mercy in all judgments, he began collecting fines for certain offenses. From this privileged beginning, the state's monopoly on the prosecution, punishment, and profit of crime began to establish itself and to reign unchallenged in even the most turbulent of places. Barons, entitled to hold "manorial court of law," took the profits of justice by requiring that offenders pay not only the victim but also a commission to their lord for effecting reconciliation. Desirous of this income, Henry II, in the 12th century, expanded the king's authority by declaring certain offenses "breaches of the king's peace," a phrase originally restricted to committing an offense within the king's presence, that might be redressed only by recourse to the king's courts; whereupon, during the course of time, fines were paid directly to the

state, and not the victim, and chastisement of the offender, rather than restitution for the victim, became the enforced redress.

Restitution and Punishment

As chastisement and restitution have, for 8 and some odd centuries, been conceptually distinguished, it is not uncommon, among those considering the matter at any length, to question whether restitution is in fact punishment. After all, it appears in form as merely a court order to pay for losses, and to many it suggests simply a scheme to rehabilitate defendants. Consequently, it seems most akin to a civil judgment, enforced by similar means, whereas a fine or imprisonment, by way of contrast, relates to the defendant's individual culpability rather than to the victim's situation.

Historically, of course, restitution or compensation by an evildoer is closely related to the concept of punishment. Only as the king or his functional equivalent began to exercise more direct control was the concept of compensation or restitution separated from the criminal law and relegated to the law of torts. And, more to the point, those in favor of restoring restitution to the panoply of criminal justice alternatives note that forced restitution is inflicted deliberately on only those found culpable for behavior that is forbidden by law. It is also noted that in the due course of such infliction, the offender is subjected to the discomfort and shame of being arrested, charged, put on trial, and forced into working and into turning over the fruits of his or her labor. Hence, coercion, censure, deprivation, and other consequences normally considered unpleasant are all inflicted on the wrongdoer, not accidentally, but just in order to impose suffering on the culpable person and to render him or her worse off than before.

Restitution and Human Dignity

Some things should not be thought of as commodities. Marketing embryos, human beings, human organs, life-preserving medical treatments, or women's reproductive capabilities are regarded, in most contexts, as too intrusive, too insensitive, or too thoughtless of the intrinsic dignity and significance of human beings. Likewise, extracting money for a criminal wrong may be considered

impersonal and demeaning. It may be considered a commodification of the human torment and bereavement occasioned by crime, and as such, it may be thought by many to denigrate society, the victim, and the perpetrator. From this perspective, such a reduction of human dignity invades our social life, changing it for the worse. It reshapes our culture, thwarting nobler forms of human relationship, reducing them to matters of monetary calculation evaluated in terms of productivity lost, cost/benefit considerations, and the market choices made by victims respecting, for example, their choices of profession or labor.

But, contrary-wise, others note that it is the understanding that people have of a social practice that determines to a very great extent their attitude toward it. For example, if reparation is understood as payment under a social contract for being a good citizen under extraordinary circumstances (i.e., victimization), such payment seems an affirmation of both personal dignity and the value of good citizenship. Similarly, if restitution is understood as a kind of endowment or grant in appreciation for good citizenship under extraordinary circumstances, its award does not seem to denigrate the individual. So perhaps it is reasoning in the wrong direction to think that people are used by money. Perhaps it is the uses that we make of money that define its impact on our culture and social life.

Restitution and Class

Perhaps the most obvious question is whether rich people will be able to commit crimes with impunity. And if the costs of a crime are so high as to burden the rich, won't the poor be unable to pay them off? Of course, those of a restitutionary bent agree that we cannot allow the particular economic position or socioeconomic background of a wrongdoer to affect substantially the making of restitution. So, the simplest answer is that there must be no restitution without work. Regardless of available resources, the convicted wrongdoer should be required to work off the restitutionary debt at whatever employment ensures a maximal output.

But even though everyone might be working to make restitution, everyone's work is not equally valued by our society. So, can't some people pay off their restitutionary debt faster than others even though they might owe the same amount? To meet

this objection, restitutionists suggest that the state first pay full restitution to each crime victim and then set about gaining reimbursement by counting all of the wrongdoer's work, of whatever market value, as paid at the same rate. This is to avoid a kind of "class bias" in the system whereby someone whose work can command a higher hourly rate on the market (say a rock singer) will not have an easier time making restitution than someone whose work is less able to demand a high rate (say a college professor). In the case of a rock singer, for example, the normal amount that he or she would make by giving a concert might be turned over to the court, which would then count only the amount that the singer would have received at minimum wage toward satisfying the restitutionary debt. The singer's work is, in effect, valued in the same way as an ordinary laborer's with the "excess profit" going toward the public good.

offender, and community that seeks to repair the harms caused by a crime—is steadily gaining credibility as a powerful alternative in the response to crime. According to Daniel van Ness and Karen Strong, the phrase *restorative justice* was launched by Albert Eglash in 1977. Restorative practices have been adopted into most criminal justice systems, especially for youth. International organizations have delivered recommendations and statements to promote the implementation of restorative principles and practices to address crime. This entry proceeds by discussing the history of restorative justice, the various definitions of restorative justice, its use in policing and prevention, and the future of restorative justice.

History

Restorative justice is not an invention of recent decades. For some authors, a reparative type of response to injustice was the mainstream in earlier times. Early small communities could not afford exclusion or enduring conflict in their midst, because the struggle for life needed intensive cooperation and mutual support. They probably tried to find constructive solutions to internal conflicts and to avoid casting out as much as possible. For several scholars, the centralizing of power gradually shifted the meaning of norm transgression from harming another and social life to breaking the King's or the Pope's law. The settlement of the aftermath of a "crime" was taken away from its main proponents, and reparation for the victim became subsidiary to punishment to enforce law compliance. In that view, the state has done much damage to the quality of conflict resolution in communities. The state stole the conflict from its rightful owners.

Other authors reject this view as being mythical and based on an unscientific approach. They suggest a history of escalating violence and revenge prompted injustice and damages that were responded to by actions to pay back, undertaken by the victims, their families, and clans. The emergence of central power then gradually blocked this violent private retaliation and was replaced by an increasingly sophisticated, legally ordered system of punishment. Violence in communities was reduced and monopolized in the hands of the state.

RESTORATIVE JUSTICE

All around the world, restorative justice—a collective reparation process involving the victim,

Restorative justice is deeply rooted in ancient wisdom, even if its predominance in practice may be uncertain. This appears also through the recent emancipation of native peoples, especially in New Zealand and in North America. Restorative justice has made their ancient traditions visible, which in many cases (but not all) are oriented toward objectives as encounter, community involvement, and reparation.

In its modern form, restorative justice reappeared in the late 1970s, and it became an increasingly important factor in practice and policy in the 1990s. Its reemergence was based on multiple roots. Victims' movements claimed an expanded role in criminal justice. Victims' rights movements were initially narrowly focused at promoting victims' rights in the conflict with the offender, and they held a strict oppositional view on victims' and offenders' interests. In their "zero-sum" approach to justice, the more attention that is paid to the offender's rights and needs, the less space there is for the victim's. Today, most victims' advocates are oriented toward a broader scope of social, personal, and juridical needs of those victimized. They now understand that making simply a coalition with the traditional criminal justice system is often counterproductive for the victims. More than imposing punishment on the offender, seeking reparation and compensation may result in deeper and continuing satisfaction. Deliberation, rather than enforcement, may contribute to mental peace.

Another source of restorative justice is communitarianism. As a reaction to the fragmentation of postmodern Western societies, some propagate the revival of community as the organic resource of informal mutual support and control. Communities are at the same time perceived as a means and as an end for restorative justice. They are a means in that communities are needed as the "niches" wherein reintegrative shaming and restorative processes can take place; they are an end, because it is believed that achieving restorative processes in a community is constructive to the revival of community life. Within the communitarian agenda, restorative justice has been inspired by religious beliefs, as appears through the spiritual basis of the Victim Offender Reconciliation Program (VORP) in Kitchener, Ontario, Canada, which is often mentioned as the grassroots origin of restorative practices, and through the publications of one of

the founding fathers of the restorative body of ideas. The communitarian agenda has also been boosted by the emancipation of native people, especially in North America and New Zealand. Their community-based, peace-oriented, and deliberation-driven ways of dealing with conflicts and norm transgression deeply influenced restorative practice and thinking.

Given its diverse roots, broad field of implementation, and currently different forms, it is not surprising that restorative justice does not seem like a clearly defined set of thoughts and implementations but as a confused, seemingly even incoherent assembly. Adding to the confusion are seemingly similar movements under banners like transformative justice, relational justice, community justice, peacemaking justice, and others.

Definitions

Only recently have practitioners and researchers recognized a fundamental commonality underlying most versions of mediation, conferencing, circles, and other reparative or compensatory practices. That is probably one of the reasons why no generally accepted definition of restorative justice exists and why different, sometimes even opposing, views exist. But if the words *restoration* and *justice* do have a meaning, it should be possible to find the key characteristics of what can be called restorative justice.

Maybe the most quoted definition is by Tony Marshall: "Restorative justice is a process whereby all the parties with a stake in a particular offense come together to resolve collectively how to deal with the aftermath of the offense and its implications for the future." This definition has two problems. First, it does not consider that the outcome of the process must be reparative or restorative. Second, Marshall's definition excludes actions that may lead to reparative outcomes without "parties coming together."

In 2002, Howard Zehr proposed another definition, which orients the process toward restoration: "Restorative justice is a process to involve, to the extent possible, those who have a stake in a specific offense and to collectively identify and address harms, needs and obligations, in order to heal and put things right as possible" (p. 37). This clearly remains a process-based definition, which

may exclude (partly) reparative actions through imposed obligations.

Gordon Bazemore and Lode Walgrave have proposed a simple and essentialist definition: "Restorative justice is every action that is primarily oriented toward doing justice by repairing the harm that has been caused by a crime" (p. 48). This definition is reduced to its most crucial characteristic, the aim of reparation, and does not mention underlying principles nor specific requirements or rights for parties. It also may include nondeliberative interventions, such as victim support, or imposed restitution or community service if it is intended as a symbolic compensation for the harm to social life.

This "maximalist" version of restorative justice is controversial. Paul McCold, for example, is strongly opposed to it and confronts it with his holistic "purist" version, uniquely based on voluntary cooperation by the stakeholders, rejecting any use of coercion under the restorative justice label. He refers to Marshall's earlier definition, and considers the deliberative and inclusionary process as the key characteristic of restorative justice. Both Walgrave and Bazemore replied that a purist vision would keep restorative justice at the margins of the social response to crime, leaving the mainstream to the traditional punitive criminal justice system.

The opposing viewpoints are ameliorated somewhat by the increasing awareness that restorativeness is not just a clear-cut feature. It is an option that may penetrate different actions in different degrees. Between fully restorative programs or systems and minimally restorative ones, graduations of partly or moderately restorative approaches exist.

Walgrave, therefore, suggests an adaptation of the earlier Bazemore and Walgrave definition and considers as restorative justice an option on doing justice after the occurrence of an offense that is primarily oriented toward repairing the individual, relational, and social harm that is caused by that offense.

In this version, the focus is shifted from "action" to "option." Restorative justice indeed is not a monopoly of certain fully restorative actions opposed to all the other nonrestorative actions. It is, on the contrary, an option, a vision, and an intention that may inspire in different degrees a variety of initiatives, programs, and systems.

The proposed definition is outcome-based, whereas most of the "restorativists" are sympathetic to the process-based approach. They all promote informal voluntary settlements as being crucial for achieving restoration maximally. The communicative potentials of mediation and family group conferences, for example, indeed favor the authentic assessment of the harm suffered and may more easily lead to a genuine agreement on how it can be reasonably repaired or compensated. The offender's acceptance to make up expresses his understanding of the wrongs committed and harms caused as well as his compliance with the social norms; the recognition of harm confirms the value and recognizes the rights of the victim. This is all much more restorative for the victim, for the community, and for the offender as well, than if the offender is simply imposed a sanction.

It is interesting to note that in the historical background and development of restorative justice, the terms *restitution*, *reparation*, *compensation*, *atonement*, *redress*, *community service*, *mediation*, and *indemnification* have been used interchangeably in the literature and that the term *restorative justice* is a fairly new one, which can mean different things, depending on the country, state, and community where such programs exist. Restorative justice is, so to speak, an umbrella term for all sorts of ways to undo the wrong caused by crimes or offenses. Restorative justice focuses on losses, repairs the damage inflicted, seeks satisfied parties, and views the victim as the central person of the whole process.

Restorative Justice and Policing/Prevention

The importance of restorative justice philosophy can be seen in the fact that it has been incorporated in newer concepts of policing, prevention programs, and within the context of justice systems.

The traditional style of policing was to keep public peace and order, enforce laws, make arrests, and provide short-term solutions to occurring problems. It ignored the old principles and aspects of the community's and citizens' welfare and their working together with the police. Dissatisfaction with the traditional policing style led to the development of community and problem-oriented policing. Elmar G. M. Weitekamp, Hans-Jürgen Kerner, and Ulrike Meier concluded that citizens want a

strong police force with a high visibility in their neighborhood and that citizens want police officers that are their friends and helpers who are prepared and willing to handle all kinds of problems within the community. These expectations can best be accomplished by adding to the existing concepts of problem- and community-oriented policing the offenders as an important party and even more important the victims of crimes. By introducing such a balanced restorative justice model, this approach includes all aspects in an integrated manner such as crime, fear of crime, crime prevention, and the improvement of the quality of life for all people who are involved.

In looking at the newest developments of restorative justice within the context of existing justice systems, one finds that they resemble, in fact, very old and ancient forms of restorative justice as used in acephalous societies and other forms of humankind: family group conferences, family conferences, peace circles, community circles, or circle hearings as used by indigenous people as well as healing justice approaches such as the Aboriginals, Maoris, Inuits, the Native Indians of North America, African tribes, and Truth and Reconciliation Commissions such as the South African one. The new concepts and models treat crime, according to Ron Claasen, as an offense against human relationships; recognize that crime is wrong and when happening can alienate the community, the family of the victim, and the offender; and further lead to damages, disrespect, disempowerment, and feelings of insecurity. The goal of the restorative justice approach is to recognize the injustice, and thus, some form of equity will be restored, leading the participants of this process to feel safer, more respected, and more empowered.

The Future of Restorative Justice

Despite the positive and exciting new developments, it has to be pointed out that so far only very little has been achieved by restorative justice. Most crimes in the world go undetected. John Braithwaite pointed out that 90% of the occurring victimizations will always be untouched by restorative justice processes since most victims are victims of white-collar crime without even realizing that they were victimized. Everybody seems to talk about

restorative justice, but in reality, one finds such approaches only here and there, and most crimes, if at all coming into the criminal justice system, are still handled in a retributive style; therefore, the days of a restorative justice paradigm as a full-fledged alternative to both the rehabilitative and retributive approaches are still far away.

Even if we would come close to such a system, it has been pointed out by numerous critiques that it is of utmost importance that procedural safeguards and standards are developed for restorative justice.

Society will also have to face offenders for whom the restorative justice approach will not work and who have to be incarcerated in order to protect citizens, communities, and societies. However, the State and its institutions should in these cases also apply a restorative justice approach as far as possible and base the reaction on a restorative justice philosophy. A good example that a restorative justice approach can be applied at all levels is the Belgium experience where they have in the prison system ways to start a healing process between the offender and the victim in very serious cases. That a restorative justice approach can also be used even in cases of severe homicide demonstrates the work of Mark Umbreit.

However, although restorative justice models seem and sound very promising in theory and achieve much better levels of satisfaction for victims, offenders, and all other persons involved in such programs, evaluations of these programs are usually plagued by one or more of the following shortcomings:

1. Despite a tremendous amount of legislation to introduce and reinforce restorative justice models and programs, they are applied in a very unsystematic manner and have not, with maybe the exception of New Zealand and Austria, gained a major role in any justice system.
2. Restorative justice models often do not serve as alternatives to incarceration and often lead to stronger, wider, and different nets of social control.
3. Restorative justice models often admit only a small number of minorities and a disproportionately high number of juveniles, first-time offenders, and property offenders.

4. Competing agencies, with unclear missions, who have different stakes in restorative justice and often compete or contradict restorative justice, harm the movement more than do restorative justice a favor.
5. Poor planning, unsystematic implementation, and even more importantly, the shortsighted evaluations of restorative justice programs constitute a major problem and are responsible for the often trivial results achieved by existing programs.

In addition to these shortcomings, several paradoxes also exist in the field of restorative justice: Germany, for example, is the only country in the world that does not use the terminology *victim-offender mediation*. If one looks at the German term used in law, literature, and practice (*Täter-Opfer Ausgleich*), it translates into English as “offender–victim mediation.” Austria uses the terminology *Aussergerichtlicher Tatausgleich*, which translates to out-of-court settlement (mediation). Although the Austrians use neutral terminology, it points out that in their mediation schemes, the victim comes first in the restorative justice process and in victim–offender mediation schemes as well. This seems to be supported by restorative justice philosophy. If, on the other hand, the focus or the central person of the whole process should be the offender, one should logically call that process offender–victim mediation, which clearly implies that the offender comes first and then the victim last. If one takes this matter seriously, one has to question the German approach toward restorative justice, since the terminology indicates that there is a lack of understanding of the basic philosophical roots of restorative justice and victim–offender mediation.

A second paradox in this context can be found in Spain and France. Jesus Trujillo points out that France and Spain use the terminology *penal mediation*. Penal mediation was introduced as a process in which the victim, the offender, and a mediator act under the control of the prosecutor. However, this constitutes a paradox since bringing together the term *penal*, which stands for punishment, and *mediation*, which stands for restoration, contradict each other.

It is a paradox that countries with well-developed and influential victim support have a mediocre

restorative justice movement, and that those countries with weak or poor victim support have a better and stronger restorative justice movement; it does nevertheless make some sense. Weitekamp pointed out one of the factors of the rediscovery of restorative justice in the last century was that the victims of crimes were completely left out of existing criminal justice programs and procedures, and they were the big losers in the justice process. Before victim–offender mediation and other forms of restorative justice were rediscovered, Margery Fry asked whether our ancestors were not wiser with reference to the extensive use of restorative justice approaches to solve problems.

This gap between victim support and restorative justice constitutes a dilemma and a good way out. To enhance the victim the best way would be if both movements would join forces. Inge Vanfraechem was one of the first to point out that both movements could and should join their forces since both would benefit from it. Although victim support often receives victims who are unwilling to go through the judicial process, they could easily be referred to restorative justice programs that handle cases not necessarily completely outside of the judicial system but certainly do not represent the judicial system. On the other hand, victim support has a lot to offer the restorative justice movement, since it provides services that cannot be provided by mediators or conference facilitators. One of the worst scenarios is that those two movements will start to compete with each other and that a power fight would start over who is more important. The losers of this battle would clearly be the victims of crimes.

Although the restorative justice movement is at this point and time stronger than ever and has so far achieved a lot, important additional improvements can be achieved in the following areas:

1. Natural or true experiments are urgently needed to determine whether victim–offender mediation and restorative justice schemes actually work better than the traditional judicial procedures.
2. Although there is some indication that the recidivism rate is not worse or even better if people participate in victim–offender mediation programs and restorative justice schemes, better studies are needed to find out more about this important aspect.

3. Quite a bit is known about levels of satisfaction of victims, offenders, and other people involved in victim–offender mediation programs and restorative justice schemes. However, this knowledge comes almost exclusively from Australia, New Zealand, and North America. Research in other countries is needed.
4. Almost nothing is known about the long-term effects of the mediation or restorative practices on the victims, offenders, and all other people who are involved or excluded from such processes.
5. Countries could implement national offices to monitor what is going on in their respective countries with regard to victim–offender mediation programs and restorative justice schemes.
6. Continued surveys could be conducted on the development of the practice of victim–offender mediation programs and restorative justice schemes.
7. Some sort of quality control for restorative justice programs as well as for laws dealing with these matters is needed.

So, where might the restorative justice movement go from here? As this entry has shown, restorative justice has great potential, but one has to watch carefully which direction the movement goes in order to evaluate the movement correctly and to prevent it from going in a direction that does not fulfill its aims.

REVICTIMIZATION

Revictimization is a serious, multifaceted, yet poorly understood public health, public safety, and criminal justice problem in the United States and abroad. Although the phenomenon has long been observed by those who work with adult victim/survivors, particularly with those who have been sexually (re)victimized and/or battered by their intimate partners, it is often framed pejoratively by directing blame toward those revictimized rather than toward those who exploit and perpetrate violence against the vulnerable. This entry provides definitions of revictimization with an emphasis on women's experiences, cites statistics regarding how often it happens, describes its consequences, discusses associated factors and theorized causes, and ends with a brief commentary on future directions.

Definitions

Repeat victimization or revictimization is the phenomenon in which individuals who have been victimized in childhood are victimized again at a subsequent point in their adult lives. The term is most often used in relation to sexual (re)victimization, although more recent conceptualizations of the phenomenon use expanded definitions that include other forms of childhood and adult mistreatment, such as neglect, physical assault, and emotional abuse.

Although repeat victimization has been recognized clinically for more than 100 years beginning with Sigmund Freud's description of "repetition compulsion," the formal study of revictimization has only begun in earnest within the last 20 years, with the first literature review of research on the topic published in 1996. The phenomenon has been conceptualized, defined, measured, and examined using multiple approaches from different disciplinary perspectives, including psychoanalysis,

feminist activism and theory, clinical psychology, criminal justice, and public health. Throughout the 1990s, scientific investigation sought to verify anecdotal observations reported by advocates and clinicians that victimized children are at significantly increased risk to be abused again in adulthood compared with those not maltreated. Although considerable evidence now exists confirming the existence of revictimization, knowledge of its causes, effective treatment and prevention strategies, as well as its myriad costs and harms to individuals, families, communities, and societies remains limited.

Revictimization has been defined using differing age ranges to delineate discrete points in a life cycle as well as how acts of victimization are conceptualized and measured in research studies. The most common definition refers to experiencing an incident or form of sexual abuse in childhood or adolescence, and then the same or different form of sexual victimization—rape, sexual assault, sexual harassment, sexual coercion—in adulthood by an intimate partner, another nonstranger, or someone not known to the victim. Recent public health approaches have defined revictimization as an incident or series of incidents of victimization, including sexual assault or abuse, physical assault, emotional abuse, and/or neglect experienced in childhood or adolescence, defined as under the age of 18 years, and at least one other discrete incident of victimization occurring at 18 years of age or older.

Child maltreatment, whether physical, sexual, psychological, and/or emotional in form, particularly when abusers are family members or care providers for disabled persons, can be an ongoing interpersonal dynamic or care-giving context rather than a single event, however, as it may be when the perpetrator is a stranger to the child. Child sexual abusers often spend years grooming their victims using increasingly invasive forms of coercive boundary violations and sexualized acts; emotional and psychological forms of abuse in (dysfunctional) families of origin are generally embedded in relationship dynamics rather than in discrete incidents. Relationship violence in adulthood, such as the control and domination of one intimate or dating partner by the other in the private sphere, and hostile environment sexual harassment in school or on the job in the public sphere are similar criminally abusive contexts. Feminists

have pointed out that gender-based violence is further situated within sociocultural structures that confer unequal social power, authority, and privileges to males and females, adults, and children, thus complexly and often negatively impacting the social responses, support, and resources afforded to those who are revictimized.

Risk and Prevalence Rates

Overall, considerable evidence exists demonstrating that among females, childhood sexual abuse (CSA) leads to an increased vulnerability for sexual revictimization in adulthood, and increasingly, evidence shows that all forms of childhood maltreatment heighten vulnerability for both sexes for repeat interpersonal victimization. Recent population-based and prospective studies continue to show that the best predictor of victimization is having been victimized at a previous time in one's life.

Just as childhood sexual victimization rates are epidemic (1 of 6 girls and 1 of 33 boys is sexually abused before they turn 18), revictimization too has been shown to exist at epidemic rates among women in general, and at elevated rates among African American, college student, disabled, economically disadvantaged, treatment-seeking, homeless, sexual minority (especially bisexual), sex worker, and military female populations.

Although most research has focused on sexualized forms of childhood maltreatment, all forms of childhood maltreatment substantially increase the risk of being revictimized. Researchers Rachel Kimerling and her colleagues reported in a 2007 study involving more than 11,000 ethnically diverse women living in California that 12.2% of all women are revictimized through physical or sexual assault. The prevalence of repeat victimization was 50.2%, compared with 14.1% among women abused for the first time during their adult years.

Experiencing physical abuse, emotional abuse, and/or neglect in childhood places individuals at a significantly higher risk for being stalked, being kidnapped, and witnessing violence as well as for being battered by an intimate partner or sexually assaulted. Furthermore, the pathways from child to adult victimization are patterned. The 2007 California revictimization study reported that although each form of childhood maltreatment

was strongly associated with at least a fivefold increase for subsequent violence in adulthood, the type of victimization a child lives through creates a significantly greater risk for experiencing the same form of abuse in adulthood. In one of the rare prospective studies on revictimization, published in 2008 (more than 1,100 men and women with documented histories of child maltreatment were followed up 30 years later), it was reported that individuals who had lived through multiple forms of maltreatment in childhood had the highest rates of revictimization in adulthood.

Effects

Increased scientific understanding of the human trauma response to interpersonal violence, specifically, that it results in a complexly interactive set of consequences with biological, psychological, interpersonal, and cultural dimensions, has significantly advanced our understanding of revictimization. Women who are revictimized experience higher levels of psychological distress and certain types of mental health disorders, including a more than twelvefold increase in posttraumatic stress disorder (PTSD), a threefold increase for depression and anxiety, and increased rates of dissociative disorders and higher rates of suicidal and addictive behaviors compared with women abused in childhood only. Revictimized adults have greater difficulty regulating their emotions and coping with stress, have poorer self-images, and exhibit greater self-blame and higher levels of shame than those victimized only in childhood or adulthood, all of which complicate and translate into an array of interpersonal challenges.

Victimization experience—especially without swift intervention—can significantly challenge a child's psycho-social and behavioral development, particularly negatively impacting her or his experience of, ability to have, and expectations regarding family and other interpersonal relationships. Revictimization also impacts people socially as well as intrapsychically, somatically, and behaviorally, and these interpersonal and situational challenges are increasingly being recognized as key contributors to the cycle of violence in which half of child victim/survivors get caught. Revictimized adults struggle more in interpersonal relationships and in private and public settings than their

nonvictimized peers. Intense feelings of social isolation and stigma, challenges assessing and responding to external threats others may pose, difficulties trusting others in general, increased risk-taking behavior and sexual dysfunction, and disrupted educational, employment, and marital lives are hallmark legacies that mark the lives of those who have been victimized repeatedly.

On the whole, revictimized individuals, female and male, are exposed to a significantly higher number of interpersonal traumatic events in adulthood compared with their non-abused peers. Living through a single form of repeat victimization often leads to deleterious effects on the victim/survivor's physical and psychological health; experiencing multiple forms of victimization has an incrementally negative impact on the victim/survivor's health and well-being. Growing evidence exists that the range of revictimization experience as well as the frequency and severity of these events has a cumulative traumatic effect on individuals. The more often one experiences a traumatic event, the greater the range and severity of the trauma-related symptoms experienced, suggesting early intervention is the key to prevention as well as to mediating traumatic impact.

Why Revictimization Occurs

Revictimization is essentially an interpersonal, social phenomenon. In an effort to understand why one in two children are revictimized in adulthood, however, the bulk of investigation and published literature on the subject has focused on maladaptive personal factors associated with a legacy of child abuse (e.g., PTSD, alcohol and drug abuse, risky sexual behavior, impaired risk recognition, dissociation, and interpersonal challenges). No single factor associated with childhood victimization has been found to distinguish those who are abused again from those who escape further maltreatment. Furthermore, this emphasis implicitly plays into entrenched "blame the victim" philosophies circulating within the larger society, and such misattribution of responsibility has serious, and stigmatizing, implications for the health and well-being of victim/survivors of violence. Victim-blaming tendencies negatively influence the reactions of those to whom the victim/survivor discloses their experience as well as

funding priorities for services and research, and social policies and practices that wield the power to hold perpetrators accountable and, presumably, to diminish their opportunity for continued criminality and abuse.

Ecological models, such as the one Liz Grauerholz developed in 2000 for repeat sexual victimization, attend to risk factors at multiple levels of social experience—personal, situational, institutional/community, and sociocultural—as they represent the array of contexts in which individuals operate. Building on this framework in their 2003 review and reformulation on the subject, Terri Messman-Moore and Patricia Long advocate for the examination of clusters of risk factors—specifically as they operate in situations involving the victim and the perpetrator—that function through their interaction to increase a victim/survivor's vulnerability to revictimization.

Messman-Moore and Long propose two primary mechanisms that functionally cluster risk factors together. Exposure risk is theorized to involve risk caused by increased contact with sexually aggressive men, for instance, in male-dominated environments, such as military bases and fraternity houses, in bars, drug dens, and other locations that people use alcohol and other drugs, and through recreational sexual activity with multiple sexual partners or by work in the sex-trade industry. Psychological vulnerability is theorized to place a victim at risk because of the perpetrator's targeting of those he identifies as psychologically vulnerable, for instance, because of intoxication, dissociation, drug use, unconsciousness, cognitive or physical disability, social stigma, low self-esteem, lack of family (particularly maternal) support, or knowledge of previous sexual abuse. Victimiziers justify their aggression by viewing a victim's freezing, incapacitation, or inability to resist as invitation, their decreased ability to respond effectively to unwanted sexual advances or threats as insincere, and knowledge of past victimization as proof of desire.

Recent research and theorization has helped to address the significant gaps in knowledge regarding the factors and processes that drive or protect against revictimization, but significantly more is necessary to develop and implement effective prevention and intervention efforts for this entrenched social problem.

Future Directions

Individuals who are caught in the cycle of (re)victimization require an intensive and disproportional set of medical, legal, mental health, employment, and other social services. Research and advocacy point toward the critical need for integrated responses created collaboratively among mental/health care, legal, education, employment, and social service systems, as well as early intervention and programs developmentally and culturally targeted for different populations.

Prospective designs capable of determining causality and how risk factors cluster, longitudinal research capable of measuring a population over time, as well as qualitative designs and case studies capable of examining repeat victimization as situated within broader dynamics of family and other forms of interpersonal violence are needed, as well as theory guided by ecological, life course, and cumulative trauma perspectives. More research is needed on male revictimization, ethnic and sexual minorities, disabled, and other vulnerable or marginalized populations.

Ultimately, however, individual and systems-level intervention, prevention, treatment, and research efforts are hindered, as is the ability of individual victim/survivors of revictimization to overcome complex legacies of cumulative traumatization, by shallow, yet widely held, perceptions that individuals caught in a cycle of (re)victimization bring it upon themselves. These cultural misperceptions too must be shifted through knowledge and compassion to end this vexing epidemic.

RISK AND PROTECTIVE FACTORS AND RESILIENCY

The prevention of criminal activity is highly dependent on a thorough understanding of how a variety of factors impact (or shape) the onset, persistence, and desistance of such activities. At the micro-level of analysis, this often constitutes focusing on the risk and protective factors associated with criminal activity. Definitively, risk factors are those variables that increase the likelihood that a criminal offense will occur. Alternatively, protective factors are those variables that function to moderate the effects of risk factors. That is, protective factors possess minimal impact in low-risk environments; in high-risk environments, however, their effects are positive and significant. Both risk and protective factors are directly related to a third term known as resiliency. Resiliency is the concept describing when individuals in high-risk environments abstain from involvement in serious criminal activity. In the most true sense of crime prevention, resilient individuals are the statistical anomalies; those individuals who because of their high risk are predicted to engage in delinquent and/or criminal activities but refrain from involvement.

Risk Factors

The concept of risk, or the interest in investigating the effects of risk factors, is not new to the fields of victimology and crime prevention. For several decades, criminologists have addressed empirical questions related to the causes of offending and

victimization and have linked this research back to the prevention of criminal activity. Each of these questions possessed at their core the intrinsic value of identifying individual, environmental, or situational factors that increase the odds of the occurrence of a crime or victimization. The logic follows that a thorough understanding of the causes of delinquency and crime will provide insight into how to reverse the impact of the causes in hopes of decreasing the undesired behavioral outcomes. To draw on an example from the medical field, if research has documented that poor eating habits and obesity lead to heart disease, it logically follows that improving a patient's eating habits should result in a decreased likelihood of future damage to the cardiac system. So, much like changing eating habits can decrease the risk of heart disease, changing the friends who one associates with can alter the risk of involvement in delinquency and crime (assuming, of course, that peer association has been found to be a significant risk factor within the field of criminology).

Although understanding the effects of risk factors on delinquency and crime is important in and of itself, criminologists have also initiated several efforts to understand how the nature of risk factors impacts delinquency and crime. Some questions that researchers have addressed are as follows: (1) Does the timing of when a risk factor is experienced matter? (2) Is there variation in the impact of risk factors from certain environments (e.g., neighborhood, family, and school)? (3) Does the probability of engaging in delinquency/crime or being victimized increase as the number of risk factors experienced increases? The answers to these questions inevitably provide policy makers with a more informed understanding of the potential programs that can be initiated to prevent crime and victimization.

The Timing of Risk Factors

Research has documented that the aggregate rate of offending increases in late childhood and into adolescence, peaks early in adulthood, and then precipitously decreases during the remainder of the life course. To help make sense of this criminological consistency, scholars have sought to understand the effects that risk factors possess on the age-crime curve. Since the 1970s, research has been accumulating

suggesting that risk factors to crime and delinquency are age-graded. That is, a particular factor might increase the risk of delinquency and crime at one particular age, yet have minimal impact on one's behavior during a later period in the life course. For example, research has documented that the effects of parenting (or poor parenting) are particularly impactful during the childhood period of the life-course development. This should make logical sense since one's parents or caregivers typically have the most impact on a child's development in the early formative years. Upon reaching adolescence, however, the impact of parenting significantly decreases, and instead, the effects of an individual's peers with whom they associate substantially increase their influence on behavioral outcomes. Although scholarly exceptions exist and a debate about strength of these influences ensues, much of the criminological community holds the belief that at some level risk factors vary in their degree of influence across the life course.

Variation of Risk Factors From Different Domains

In addition to examining how risks differ according to *when* they emerge across the life course, research has also documented the variability in importance associated with *where* risks develop. Although scholars have generally investigated the sources of risk from a variety of different locations, four domains seem to capture the majority of scholarly attention. First, a lengthy research agenda has developed focusing on the sources of risk located within the individual. In fact, the interpersonal deficiencies within individuals have been found to have both biological and psychological roots. Second, since much of the early development of human behavior occurs within the household, a substantial interest in the identification of risk factors has occurred while focusing on the impact of the family (i.e., parents). Third, as individuals transition through developmental stages, and in particular from childhood to adolescence, scholars have emphasized a focus on the influence that one's peers have on a variety of behavioral outcomes including crime and victimization. Finally, a longstanding sociological tradition has pointed to the environment, particularly the neighborhood, as a source of risk that shapes human

behavior. Combined, these four areas arguably account for the majority of sources through which risks can manifest and impact the development of delinquent and criminal behavior.

The Accumulation of Multiple Risk Factors

Although risks have the potential to develop and impact human behavior from a variety of different domains, the literature has failed to account for the existence of a single robust predictor. For example, although associating with delinquent peers has been found to be correlated with an increased likelihood of participating in criminal activity, the existence of this factor alone is not a powerful predictor of these same behaviors. As such, research has documented that criminality is more highly predictive when individuals experience the accumulation of risk factors. That is, the prevalence of criminal activity increases as individual's exposure to risk increases.

Scholarly research has revealed that the probability of engaging in delinquency and other problem behaviors is directly associated with the number of risk factors to which an individual is exposed. In past research assessing the prevalence of psychiatric disorders in children, scholars have isolated six family variables: marital discord, low socioeconomic status, large family size, paternal criminality, maternal psychiatric disorder, and child welfare intervention. This research found that the rates of disorder were a function of the number of risks to which the child had been exposed. Children exposed to an isolated familial risk were no more likely to suffer from psychiatric illness than those not exposed to any risk factor; the presence of two or three factors occurring in collaboration, however, produced a fourfold increase in the prevalence rates, and four or more risk factors generated a tenfold increase. Research focusing on crime and victimization has echoed these findings and has supported the assertion that the probability of occurrence increases substantially with each additional risk factor.

Protective Factors

The concept of protection, or the interest in understanding how protective factors moderate the effects of risk, is also not new to the fields of

victimology and crime prevention. Although the focus on protective factors is primarily rooted in the developmental psychopathology literature, traditional criminological research has also directed attention to the potential influence of protective factors within high-risk environments. For example, more than 50 years ago, criminological research examined the effects that variables might have in reducing the likelihood for youths to be delinquent. This research generally suggested that boys with good self-concepts were less likely to be delinquent than those having poorly developed self-concepts. Although not necessarily considered protective factor research at the time, early studies like this provided the criminological foundation through which protective factors potentially ameliorate the effects of residing within high-risk environments.

The theoretical foundation of the impact that protective factors possess is rooted in their ability to counteract the effects of high-risk environments. As identified, protective factors are those variables that serve to buffer, moderate, or insulate individuals from high-risk status. This conceptualization suggests that protective factors become impactful after the establishment of a particularly high level of risk. In fact, the higher the level of risk, the more likely it is that protective factors are capable of moderating the effects that risk factors possess. Stated differently, it is within particularly risky environments that protective factors function to moderate an individual's likelihood of developing problems.

Conceptualizing Protective Factors

Although the theoretical role of protective factors has been generally accepted among scholars working in this scholarly area, much less consensus exists surrounding the conceptualization and operationalization of these factors. Scholarly differences particularly center on the separation of risk factors from protective factors during the investigation of the independent effects of the latter (i.e., protective factors) on problem behaviors. Stated differently, a subset of scholars exists comprising those who support the operationalization of protective factors as the absence of risk or the opposite ends of a risk factor. For example, these scholars might consider low IQ as a risk that

enhances or increases the probability of manifesting problem behaviors, whereas a high IQ buffers or reduces the likelihood of such behaviors. Similarly, the presence of a caring emotional reference person has been considered an important protective factor against psychopathology, whereas the absence of such an individual is viewed as a substantial risk. Conceptualizing a protective factor as the opposite end of a risk factor clearly calls into question whether it is methodologically appropriate to consider a variable to be both a risk and a protective factor.

Another subset of scholars exists, however, comprising those who put forth an argument in support of the view that risk and protective factors are conceptually distinct from one another as opposed to opposite ends of a single dimension. According to this group of scholars, protective factors are considered independent variables that have both direct effects on problem behaviors or can moderate the relationship between risk factors and behavior. This conceptualization also allows factors to be protective only if they differentiate between maladapted and adapted (i.e., delinquents and nondelinquents) individuals who both experience equal levels of high risk.

Variation in Protective Factors Across Age and Sex

In light of these methodological issues, research indicates that the effects of protective factors should not be viewed equally across various populations. That is, similar to the impact of risk, the effects of protective factors seem to vary according to a variety of demographic characteristics, including age and sex. Not only does vulnerability shift in accordance with these characteristics, but the availability and reliance on factors insulating against risk also change. Much like risk, different protective factors manifest different degrees of impact at different developmental stages. In fact, research has documented that the importance and reliance on protective factors varies across different life stages. For example, as individuals move beyond the family sphere and increasingly associate with their peers, their opportunities for protection against risk change accordingly. The age of the individual additionally affects how they appraise stressful experiences and the coping

resources available. As such, it is important to investigate which protective factors are important at different stages of development.

Scholars have additionally identified how susceptibilities and adaptations differ according to an individual's sex. Findings suggest that under high-stress situations, boys are typically more likely to manifest disruptive or aggressive behavior, whereas girls are more likely to experience higher levels of anxiety or depression. Studies have also suggested that girls have been found to be more resilient than boys during childhood; however, they are more vulnerable during adolescence. In reference to protective effects, research has also directed attention to how protective factors within the individual (e.g., temperament, cognitive skills, and self-esteem) positively impacted the coping abilities for high-risk females, whereas outside sources of support were more important in the lives of high-risk males. These findings seem to suggest that sex differences affect the vulnerabilities and the protective resources for both males and females.

Resiliency

A variety of literatures have contributed to formulating the foundation of resiliency research. First, similar to the origin of risk-related research, the investigation of resiliency in part emerged in epidemiological research where studies occurred relating to individuals' vulnerability to coronary heart disease. For example, research examining individuals for a 20-year period has found that more serious patterns of illness evolved from individuals with higher susceptibilities, whereas resilient individuals experienced lower levels of illness. It was also observed that a small proportion of individuals survived major changes in relationships and deprivations without exhibiting any overt illness. Related research has found that this resilient behavior was associated within individuals who had no history of preexisting vulnerabilities and who had the presence of personality characteristics that buffered them from a variety of negative life circumstances.

Second, research on schizophrenia, poverty, and responses to trauma have also contributed to our understanding of how individuals adapt to stressful or adverse situations. Scholars examining the effects of schizophrenia had been primarily interested in

the majority of individuals evidencing maladaptive behavior. Early studies generally addressed the precursors and correlates of schizophrenic behavior while in part ignoring the small subset of patients exhibiting recovery and adaptive patterns. During the early 1970s, however, researchers embarked on a scholarly mission to formulate an explanation for how a small portion of individuals, despite their schizophrenic diagnosis, functioned competently in work, social situations, and their capacity to fulfill a variety of responsibilities. Although the term “resilience” was not extended to the characterization of such behavior, the patterns of adaptation and recovery clearly provided a foundation for future resiliency research.

Third, the particular stresses associated with chronic poverty exemplified an additional area of research that led to studies investigating resiliency. Despite the substantial number of social and economic deprivations associated with chronic poverty, a considerable proportion of youths have been identified to exhibit positive behaviors across the life course. In examining 167 adolescents who experienced the Great Depression, researchers have found that individuals who survived and functioned competently sought out the companionship and advice among individuals outside of the family. Moreover, an individual’s personal assets also played an important role in their ability to remain resilient. For example, a substantial number of youths successfully adapted to the adversities they faced within very low to lower socioeconomic environments. These studies seem to suggest that escape from risky environments is possible if individuals possess certain individual traits.

One final area of research that has contributed to the foundation of resiliency has been studies investigating adaptive functioning in individuals exposed to a variety of life traumas. The nature of the traumas experienced could be a function of the natural environment (e.g., earthquakes or hurricanes) or socially constructed (e.g., wars and revolutions). Research provides detailed accounts of how poor minority children succeed in school and in raising a family despite traumas experienced throughout the course of their development. Studies have also documented the successful life histories of adults who had previously experienced the pains of the Holocaust as children. Again, although

expectations of maladaptive behavior are relatively high among these populations, it was observed that some individuals overcome and virtually thrive in such situations.

Despite the historical significance of these diverse areas of research in providing a foundation to study resilient youth, the more contemporary roots of resilience can be traced to work by developmental psychopathologists. While observing that some individuals, although equally exposed to high-risk environments, failed to manifest psychopathological behavior, several scholars organized a research agenda to investigate variables that might ameliorate the effects of multiple risk factors. In other words, scholars began to embrace the idea that competence and maladjustment are best studied together—the study of one informing and improving the study of the other. As such, developmental psychopathologists initiated a systematic effort to investigate factors that produced successful outcomes in children and adolescents at risk. Recognizing that previous researchers were mainly interested in explaining problem behavior through variations in risk alone, this more contemporary developmental approach placed the effects of protective factors at the forefront of analytical models. In short, the increasingly prominent role of the developmental perspective has fostered an interest in the diversity of developmental outcomes and in the complexities of different pathways of human behavior. These literatures appropriately suggest that successful adaptation despite extensive adversity is one developmental pathway that is worthy of empirical understanding. As such, investigators began to explore the many possibilities through which protective factors theoretically influenced resiliency.

Conclusion

The scholarly evidence associated with risk and protective factors and resilience can be particularly instructive to the development of policies to prevent crime and victimization. Programs designed to reduce risk or enhance protection (particularly in high-risk environments) should be capable of producing intended results and promote resiliency.

ROBBERY

Robbery is the crime of seizing property through violence, fear, or intimidation. The term *rob* is derived from the German *raub* (“clothing”) since garments were a frequent target of robbers before factory mass production techniques decreased the production costs and the value of clothing. Robbery should not be confused with simple theft (which involves the taking of property without force, violence, or intimidation) or burglary (which

does not require the presence of a victim and is associated with the taking of property from a domicile or place of business). According to the U.S. Unified Crime Reporting (UCR) Program, the United States suffered 445,125 robberies, with a rate of 2.8 robberies per 1,000 people age 12 years and older. Depending on individual state statutes, the use of a lethal weapon may elevate the charge of robbery to *armed* robbery, whereas physical assault on the victim during the course of robbery will elevate the charge to *aggravated* robbery. As with other forms of interpersonal crime (homicide, sexual assault, aggravated assault), robbery places the victim in direct confrontation with the offender and is often a traumatizing experience.

Prevalence and Statistics

According to the FBI's 2007 statistics, although the estimated number of robberies (445,125) decreased 0.5% from the 2006 estimate, the 5-year robbery trend (2003 to 2007 data) showed an increase of 7.5%. The average victim lost \$1,321 per robbery with banks suffering the highest average dollar loss (\$4,201). The total U.S. losses attributed to robbery victims in the United States was estimated at \$588 million, not taking into account associated losses because of hospitalization, insurance costs, and court and law enforcement costs, which would push the total annualized loss to more than \$4 billion. Robbery is a violent crime, and overwhelmingly, firearms are the tool of choice for robbers (42.8%).

Where Robbery Occurs

Common *street robbery* (meaning that the offense occurs between one or more individuals “outside” a domicile or place of business) comprises some 44% of all robberies. The overwhelming majority of street robberies occur in poor, urban neighborhoods where police protection is scarce and populations are concentrated. The second most common location for robberies to occur are in commercial establishments such as banks (2.1%), gas stations (2.6%), convenience stores (5.6%), and commercial houses (13.9%), which includes supermarkets, department stores, and restaurants. The remainder of offenses occur in residences (15.2%, commonly

referred to as “home invasions”) or as miscellaneous (16.8%, categorized as such because the locations are not easily categorizable or are not properly recorded by law enforcement personnel).

Specialized Forms

Robbery can be broken down into several subcategories based on the characteristics of the victim. From a legal standpoint, most of these offenses will fall under the classification of robbery or aggravated robbery, but some (like carjacking) may receive their own statutory designations in some states, while others (such as bank robbery) fall under federal jurisdiction.

Drug Robbery

Drug robberies are those offenses that occur between offenders where the victim is a drug dealer who is targeted for his or her stash of drugs and money. Drug dealers relieved of their drugs and ill-gotten monetary gains make excellent targets because they cannot go to the police to report their victimization, making them part of what criminologists refer to as the “dark figure” of crime (i.e., those offenses that remain uncategorized or uncounted in common crime statistics). Their importance in the spread of violence in urban neighborhoods has been the topic of recent research, as victimized drug dealers, unable to turn to the police for help, often engage in retaliation to recoup their losses and maintain their reputations.

Carjacking

Carjacking, the taking of a vehicle from an individual by force or threat of force, has received a great deal of attention from the public and law enforcement in the past 2 decades. This is partly because of several well-publicized and notorious carjackings. For example, in 1992, Pamela Basu, on her way to dropping her daughter off at preschool, was carjacked at an intersection in broad daylight by two men. Her baby daughter was tossed from the vehicle, but Basu was entangled in her seatbelt and was dragged to her death. The crime was featured prominently in national newspapers and *Time* magazine. That same year a law

was passed making carjacking a federal crime. The offense also received increased attention as the result of a Bureau of Justice study, which estimated that, between 1987 and 1992, about 35,000 carjacking attempts took place and, between 1992 and 1996, about 49,000 attempts took place (an alarming 40% increase). Offenders report engaging in carjacking for a variety of reasons from using the vehicles to engage in subsequent crimes to selling the vehicles to chop shops. In many cases, they prefer taking vehicles by force (rather than engaging in auto theft by hotwiring a car) because doing so provides them with the vehicle’s keys, making them more valuable for resale.

Bank Robbery

Any form of robbery occurring in financial institutions such as commercial banks, mutual savings banks, savings and loan associations, and credit unions constitutes bank robbery. Bank robbery is on average four times as lucrative for offenders as common street robbery, but because the offense is a federal offense (subject to the Federal Bank Robbery and Incidental Crimes Statute) and because banks employ exceptional security measures, the offense is rare (comprising only 2.1% of all robberies). FBI statistics from 2006 to 2007 indicate that a note is used in more than 50% of all incidents; a firearm is used in roughly 25% of incidents; and robbers threaten to use a weapon in roughly 80% of incidents. The most common day of the week for a bank robbery to occur is Friday, and the most common time of day for a bank robbery to occur is between 9:00 am and 11:00 am. Despite portrayals of bank robberies in film and television, it is exceedingly rare for hostages to be taken (less than 1% of the time) and nearly as rare for individuals to be injured or killed.

ROUTINE ACTIVITIES THEORY

The routine activities theory (which is also referred to as “routine activity theory”) is both a micro-level approach that states that crime happens when three elements—a likely offender, a suitable target, and the absence of a capable guardian—converge in time and space and a macro-level approach that examines broad changes in society and how these lead to changes in community life that create new opportunities for crime. The approach is one of the “opportunity” theories of crime (along with rational choice and crime pattern theories) and is included in the group of theories referred to as “environmental criminology” (which includes the three opportunity theories, situational crime prevention, and victimization theories that focus on lifestyles). Unlike theories of *criminality*, which attempt to explain why some people have a propensity to commit crime while others do not, routine activities is a theory of *crime*—that is, it focuses on both broad and situational reasons for the occurrence of *crime events*.

This entry begins by discussing the main assumptions of routine activities while presenting the origin and evolution of the approach. Then the elements, both the original components and the ones added as the approach evolved, are defined, and their links to crime prevention practice are explored. Finally, the strengths and weaknesses of the approach are presented.

History

The routine activities approach was first presented by sociologists Lawrence Cohen and Marcus Felson in a 1979 article in the prestigious journal *American Sociological Review*. The main purpose of the article was to explain why there were dramatic increases in crime, despite improvements

during 1960 to 1975 in the social conditions that were thought to contribute to crime. Rather unexpectedly, although poverty and unemployment dropped in urban areas, and levels of education and income increased, the rates of violent crime (robbery, aggravated assault, forcible rape, and homicide) grew between 164% and 263%, as did property crime—burglary alone increased 200%. It was clear that the mainstream theories used by criminologists to explain crime, theories that pointed to “root causes” such as poverty, blocked opportunities, and the like, were inadequate to explain these rapid increases in violent crime or property crime.

Cohen and Felson offered an alternative explanation. Drawing heavily from the work of the early human ecologist, Amos Hawley, and bringing in ideas from the work of scholars in the Chicago School (such as Parks and Burgess) who looked at the relationship between humans and the environment, Cohen and Felson argued that the increase in crime rates could be attributed to changes in social and technological patterns.

The *routine activities* of people, the “recurrent and prevalent activities” that people do to meet their needs, had changed. Routine activities refer to day-to-day things such as going to work or school, shopping, socializing, and playing. They can occur at home or away from home. During the 1960s, the routine activities of a large number of people in the American population changed in ways that resulted in a “dispersion of activities away from households.” Specifically, more women entered the workforce or post-secondary education, and there were more households of only one person. People also traveled more.

The consequence of this shift in routine activities away from the home was that there was less guardianship of those homes, which made these homes more attractive targets for burglars. Children and teenagers were less supervised as mothers moved into the workplace in large numbers. This had two results. First, it increased the risk of victimization of youth because no adults were around to protect them, and second, it allowed youth to engage in criminal activity more readily because no adults were monitoring their behavior.

Not only did social changes appear on the home front, they were manifested in public life. Women who started working outside the home and going

to school became more suitable targets for opportunistic offenders, as did private vehicles used in commuting.

Routine activities theory also addresses how crime rates are affected by technological changes. Cohen and Felson found that the characteristics of “durable goods” (such as television sets and cars) were strongly associated with levels of property crime. Consumer goods became more widely owned, smaller, and lighter. Not only did the number of targets increase, the targets became more *suitable* to likely offenders. The way the increasing number of goods sold changed too. The number of stores selling these durable goods remained fairly constant, and there were fewer salespeople on the floor to tend to customers. Also, retailing shifted to more of a self-service approach, which brought more customers in closer contact with more products. The result of decreased supervision of customers and greater customer access to goods was increased shoplifting.

As was mentioned, a key difference between the routine activities approach and most explanations of crime is that very little emphasis is placed on offenders. Instead, the role of temporal and spatial factors is stressed. Indeed, this theme underlies the constellation of theories associated with routine activities, which asserts that crime cannot be explained solely in terms of characteristics of offenders, but that environmental factors are as, or more, important. Patterns of criminal behavior obviously vary from place to place. Where you park your car makes a big difference to the likelihood that it will be stolen or broken into. Your own locked garage is the safest place; a public parking lot is the most dangerous place. Risk varies across different time periods as well. Some places are safe during the day but dangerous at night, largely because of the nature of the land use and who is using the space. For example, there may be low rates of victimization in a downtown park during business hours. People using the park would be mostly engaged in benign activities, such as eating lunch, selling food and drink from carts, feeding pigeons, and so on. Although there are scores of suitable targets, there are also many capable guardians. Later in the day, when the offices close and the business people and vendors go home, a different group of people occupy the park. The staggering drunks and

straggling commuters are suitable targets, and given the lack of capable guardians, victimization is much more likely.

Evolution

There have been alterations to the routine activities approach since 1979 in response to contributions from other scholars and theorists. First, the approach has been broadened in recognition of the important theoretical links between routine activities and other approaches (such as rational choice and crime pattern theory) and, at the same time, has moved away from its roots in sociology. Although the original version of routine activities had only micro- and macro-level aspects, recent iterations have taken into account offender decision making, journey to crime, the geography of crime, and situational crime prevention. In elaborations of the macro-level components of the approach, Felson has explored how increases in human density, from villages to small towns to large cities (or the “divergent metropolis”), have created new opportunities for crime. For example, changes in land use and zoning as cities got bigger and more complex have resulted in residential areas being located far away from job locations. This leads to people spending more time commuting (which reduces guardianship of their home and increases the risk of predation by strangers), and more people relying on personal vehicles, which are then parked for hours at a stretch in untended parking lots.

Second, new elements have been added. One significant change was the incorporation of a fourth element—the *intimate handler*—based on concepts from Travis Hirschi’s control theory. This theory has four components—attachment, commitment, involvement, and belief—that together explain how families, communities, and society as a whole control people’s behavior through informal ways. What makes this control effective is that people fear what will happen to their futures or relationships with friends and family if they behave badly. Also, encouraging participation in conventional activities puts limits on available options about how to spend one’s time, and manipulating belief systems makes people feel guilty when they are bad. The intimate handler is someone who knows use well enough to know what varieties of

informal control will work best to ensure law-abiding behavior.

A more recent addition to routine activities, the *place manager*, was suggested by the work of John Eck. The place manager is someone who has responsibility over a particular space. This differs from the capable guardian in that it is not the target that the place manager is protecting, but the location where the suitable target and likely offender converge. Examples of place managers include doormen, receptionists, janitors, security guards, and building superintendents.

Adding place managers and intimate handlers to the original conception of routine activities (a likely offender and suitable target converging in time and space in the absence of a capable guardian) creates what is called “Eck’s Triplets,” wherein crime is discouraged when the likely offender is supervised by the intimate handler, the suitable target is protected by the capable guardian, and the time and space where the convergence occurs is monitored by the place manager.

Original Elements

The micro-level aspect of routine activities states that a crime event can only happen when a *likely offender* and a *suitable target* come together in a particular place and time, and there is no *capable guardian* there to prevent an interaction between the offender and the target. On the face of it, this is an extremely simplistic model for crime. But this is a strength of the theory, for it points to very straightforward crime prevention measures. If even one of the three sides of the “crime triangle” can be removed, then the crime event does not occur.

Likely Offender

A likely offender is someone who has both the propensity and the ability to commit a crime. If a crime actually happens, it is because the likely offender finds a situation where there is a suitable target and no capable guardian around to prevent the interaction. The approach assumes that there is a ready supply of people who are likely offenders. Why some people are inclined to commit crime while others are not so predisposed is not a focus of routine activities, and attempting to reduce crime by making people “better” is explicitly

rejected by routine activities. For crime prevention, the likely offender is relevant in that the perceptions of this individual determine whether a target is perceived as suitable or a guardian perceived as capable. In addition, the role of *handlers* in controlling and supervising likely offenders has taken on importance as the theory evolved.

Suitable Target

A suitable target can be a person or an object. It is the characteristics of targets that make them attractive to likely offenders. Cohen and Felson introduced the acronym VIVA to simplify these qualities, which include value, inertia, visibility, and access.

Value

Objects that can be easily converted to cash are highly prized by thieves. Recognition of this has led crime prevention practitioners to disrupt markets for stolen goods (such as pawn shops, flea markets, and increasingly, Internet sites where people sell second-hand items) in an attempt to make it harder to exchange these goods for money. Similarly, programs like *Operation Identification*, wherein people mark their property with a unique code (like a driver’s license number), are designed to reduce the value of objects to thieves because objects are harder to fence if they are marked.

For violent offenders, some potential victims have more value than others. For example, rapists tend to prefer younger women. A suitable target for an armed robber is someone who is expected to be carrying cash or other valuables.

Inertia

This refers generally to the size and weight of an item and, specifically, to how easily the item can be removed from the area. The smaller and lighter an object, the more suitable it is to a thief, as less effort is needed to carry it away. Heavy objects are less desirable, although not if they have functioning wheels. Drivers who use devices that prevent their vehicles from being shifted into gear are relying on the principle of inertia—it is very difficult to move a car if the wheels cannot rotate. Retailers of expensive fur and leather clothing often chain the garments down, thus substantially increasing the inertia of the items.

Visibility

A potential thief has to see an object before assessing whether it is a suitable target. If the item is not visible, it is less vulnerable to be stolen. Around the holiday season, shoppers are warned to lock their purchases in the trunk; failure to do so alerts thieves to the presence of goods worth stealing and can result in car break-ins. Pickpockets have been known to observe crowds in proximity to signs warning of pickpocketing. The instinct of many people is to check if their wallets are still there upon reading such a sign. This has the effect of making visible what was previously hidden in a pocket or handbag.

Access

The more easily a thief can get to an item, the more suitable that item is as a target. Stores lock their jewelry in display cases. Homeowners install solid-core doors and strong deadbolts. These are examples of target hardening, which reduces accessibility and the attractiveness of the target.

Capable Guardian

A capable guardian is someone who prevents the convergence in time and space of a likely offender and a suitable target. Most often, we are capable guardians of our own belongings and property. Those around us, such as family, friends, and co-workers, can also function as capable guardians. It should be noted that the routine activities approach is explicit in stating that police officers, because they so rarely detect crime as it is happening, are rarely capable guardians.

The absence of a capable guardian can result in a crime because the likely offender and suitable target are alone together. For crime prevention, increasing the capability of guardianship is important. In many university libraries, signs are posted warning patrons of the dangers of leaving belongings unattended. Some parents install hidden closed-circuit video cameras so as to better observe their children's babysitters.

Newer Elements

Handler

The handler is someone who exerts some influence on a likely offender by virtue of knowing the

offender well enough to act as a curb on criminal behavior. Examples include parents, adults in the community, and even peers. The key is that the handler must know who the potential offender is. Offenders can easily avoid the influence of handlers by going to another part of the community where no one knows or recognizes them. The growth in human settlements from villages to large, sprawling urban areas, coupled with increased car ownership and part-time jobs that provide disposable income, have made it a simple matter for youth to escape the supervision of handlers.

In terms of crime prevention, much youth crime takes place after school but before parents get home from work when there is little supervision of teenagers. After-school programs are an example of increasing the capacity of handlers to exert control over their charges.

Place Managers

Place managers are people who have some level of responsibility for a space. They prevent the convergence in time and space of likely offenders and suitable targets. The effectiveness of place managers varies by how much they feel responsible for the place. Those with diffuse responsibility are less effective than those who own the property or those who have contractual or employment-based duties to look at the space. To prevent crime in neighborhoods, there is much to be said for on-site managers in apartment buildings, particularly if the manager is motivated to keep the property free from crime. Resident owners are even better.

Strengths and Weaknesses

Routine activities theory has tremendous utility for crime prevention, largely because the straightforward nature of the micro-level aspect of the approach points to specific measures that can be taken. Targets can be made less suitable, guardians more capable, place managers more observant, and handlers more effective, all without undertaking the difficult task of trying to make people better.

Routine activities, as well as other theories of crime mentioned in this entry, are often criticized for neglecting the "root causes" of crime (e.g.,

poor parenting, poverty, and blocked opportunities). In addition, because routine activities theory assumes that offender motivation is irrelevant, opponents argue that it fails to take into account differences in disposition. However, it should be noted that the approach does not actually claim that everyone is equal in terms of proclivity toward crime; it just deems differences in levels of motivation not important.

RURAL CRIME

When most people think of crime, they think of urban crime. In particular, they think of urban street crime committed by strangers, young toughs brandishing a knife or a gun. Crime in rural areas is not what most people think of when they think of crime, but rural crime is real and understanding rural crime is important for several reasons.

First, understanding rural crime is important because of the large number of people affected. Although only about 20% of the population of the United States is rural, the number of people living in rural areas is greater than the number of people in any minority group in the United States and is greater than the populations of Canada, Spain, Colombia, or Australia. Although in the minds of many crime is tied to central cities, only about 30% of the U.S. population lives in central cities, which hardly makes them representative of the United States as a whole.

Second, what happens in rural areas may have considerable implications for the rest of the country. For example, drugs are often smuggled into the United States through rural border crossings, and some drugs, such as marijuana and methamphetamine, are manufactured in rural areas. Rural areas are also prime locations for terrorist attacks, including those from domestic antigovernment groups. Many of the 103 nuclear plants in the United States are in rural areas, and the successful sabotage of any one might release contamination that would affect millions of people. Destroying just two dams on the Colorado River would damage the water supply for more than 25 million people. Food production has become increasingly concentrated in the United States, with just a few rural communities serving as home to meat processing plants that supply the rest of the nation. Contaminating meat in any of these plants would threaten the health of millions of Americans.

Finally, although there is an image of rural crime as infrequent and of only minor seriousness, this is not universally true. Although on average crime is lower, there are pockets of rural America with very high crime rates. For example, of the 30 counties with the highest homicide rates, most are rural, even though the homicide rate in the majority of rural counties is relatively low. Domestic

violence and drug use seem to be equally common in rural and urban areas, but services to treat drug users and the victims of domestic violence are less available in rural areas.

What Makes Rural Unique?

Most crimes that occur in large cities can be found in rural areas, and there are many respects in which rural and urban citizens share a common culture. However, there are respects in which rural and urban are different. The most obvious difference is geography. By definition the rural population is less densely packed, as are rural services. If someone is shot or stabbed in a rural area, spotty cell phone service may make it difficult to contact help, an ambulance will take longer to arrive at the scene, and the hospital will be farther away. Thus, an injury that would be quickly treated in a city may result in death in the countryside—taking what would be aggravated assault in the city and turning it into a murder in the country.

Rural and urban areas also differ in regard to guns. Gun ownership is much more common in rural areas. However, when compared with cities, guns are less likely to be used in crime in rural areas. Guns are simply viewed differently in the two areas.

Poverty also takes on a different meaning in rural areas. Although poverty can be found in communities of all sizes, some of the deepest pockets of poverty can be found in rural areas. At the same time, rural areas adjacent to larger cities often have considerable wealth. But, just as guns have a different meaning in rural areas, so does poverty. In large cities, poverty is often linked to crime, including violence. That link is much weaker or even nonexistent in rural areas. In short, poverty seems to drive crime in large cities but not in rural areas.

Finally, understanding rural crime requires recognizing that not all rural areas are alike. In fact, there are more differences across rural areas than across cities. Take the example of race. Most large cities are characterized by racial diversity. There is great diversity within a given city, but cities overall tend to be relatively similar in this regard. In rural areas, some communities are predominantly White, some predominantly Hispanic, some predominantly Black, and so on. Differences across rural

areas on a variety of factors make it difficult to give general statements that apply to all rural areas. With this limitation in mind, let us turn our attention to some crimes that are of special concern in rural areas.

Rural Crimes

Considering first overall crime patterns, it is true that both violent and property crime occur less often in rural areas than in cities. The rate of violent crime is four times higher in cities, and the rate of property crime is three times higher in cities. Although the level of crime in communities of all sizes changes over time, both violent and property crime change less in rural areas than in cities. Urban and rural crime rates have been coming closer together in recent years, but this has more to do with changes in urban rates than with changes in rural crime rates. Going beyond these general patterns, several specific crimes deserve mention.

Domestic Violence

Police reports indicate that domestic violence is four times more frequent in rural areas compared with the largest cities. Self-report data suggest the rates of domestic violence may be similar across communities of varying sizes. Whatever the true count, domestic violence is a serious concern in rural America and stands in stark contrast to the much lower level of other types of violence. Rural domestic violence is also problematic because there are fewer places for abuse victims to turn and police resources are limited.

Driving Under the Influence

Rural residents generally lack public transportation and often must travel some distance for work, food, and other services. They depend heavily on cars and often travel at high speeds on poorly lit two-lane roads. One consequence is a high rate of accidents resulting from driving under the influence of alcohol (DUI). Rural DUI arrest rates are more than double those in large cities. DUI is a particular concern for rural youth, who are more likely to use alcohol than their urban counterparts. This group is already at a higher risk for auto accidents because of their age, lack of driving experience, and the

need to travel farther distances by car than their urban counterparts.

Illicit Drugs

In the past, it was believed that rural youth were less likely to use illicit drugs than were urban youth, with the exception of stimulants. More recent evidence suggests that rural youth are more likely than urban youth to use a variety of drugs, including marijuana, cocaine, heroin, and amphetamines. Particularly troubling are reports that rural youth are more likely to inject drugs, a practice that sets the stage for the spread of HIV and generally is a faster path to addiction. Among adults, the use of most drugs is similar across urban and rural areas, with a notable exception. Methamphetamine use is substantially higher among both rural youth and adults, when compared with use by urban residents. This is particularly true in the Midwest where a dramatic increase in methamphetamine use began in the 1990s. Historically, waves of stimulant drug use have been followed by waves of narcotic drug use. There is some evidence that the rural methamphetamine problem of the late 1990s is being replaced by a problem with prescription narcotics, such as Oxycontin.

Rural areas are also distinct from urban areas in the extent to which drugs are manufactured. Between 1981 and 2006, illicit marijuana production in the United States has increased by tenfold and the value of the marijuana crop exceeds that of corn and wheat combined. In addition to fueling drug use, methamphetamine production in rural areas threatens the environment and the physical safety of citizens. Toxic chemicals used in methamphetamine production can contaminate the ground and groundwater in rural areas. Fires and explosions sometimes occur in the process of manufacturing methamphetamine and the need for supplies to make the drug encourages shoplifting and theft. In 2006 the federal government required stricter control over the sale of ephedrine-based cold medicines because ephedrine is a key ingredient in the manufacture of methamphetamine. These restrictions have reduced but have not eliminated domestic methamphetamine production; in fact, they have facilitated the rise of criminal networks that import the drug from Mexico and Canada. These networks have the potential to bring

violence connected to the drug business into the heartland. Finally, rural areas continue to manufacture illegal alcohol. Although some might think this is a thing of the past, it continues to be a multimillion-dollar business.

Agricultural Crime

Although most types of crime can occur in communities of any size, agricultural crime is primarily rural, but the costs can be staggering. Modern farm equipment is technologically advanced, with high-end machinery equipped with air conditioning, computers, and global positioning satellite systems. A fully equipped tractor may cost as much as some people spend for a house. Today's herbicides are so concentrated, and expensive, that a pickup truck may hold as much as half a million dollars worth of the chemicals. On a smaller scale, thieves take fuel, produce, livestock, and tools. Despite annual losses that easily exceed tens of millions of dollars, little research on agricultural crime has been conducted in the United States since the 1980s. Thus, the true nature and extent of the problem has not been carefully measured or documented.

Future Research

To the extent that researchers, policy makers, and the media have focused on inner-city crime, they have ignored a part of society where crime is an issue and where crime has implications for the rest of society. It would be beneficial for not only the 60 million people who live in rural America but also for the country as a whole for future criminological research to focus on rural crime as well inner-city crime.

S

SAFER CITIES PROGRAM

Launched in 1998, the British government's Safer Cities program was an experiment designed to test the local level multiagency partnership approach to reducing crime in England and Wales. Monitoring, data gathering, and scheme/project/program evaluation components were all designed into the program from the outset.

Definitions

Safer Cities comprised phase 1 and phase 2. The program refers to the scheme itself, its funding, and management. The projects are the individual cities, towns, and boroughs in England and Wales that received funding from the program. Safer Cities schemes are the various crime-reduction initiatives on which the project coordinators, advised by their multiagency steering committees, spent the Safer Cities funds.

Historical Perspectives

Influences behind the U.K. partnership approach to crime prevention can be found in 1960s research in the United States by Albert Reiss, and in the United Kingdom in the later work of Ronald Clarke and Mike Hough, which reasoned that uniformed foot-patrol policing is ineffective in preventing crime.

Clarke and Hough concluded that a patrolling policeman in London would, on average, pass

within 100 yards of a burglar breaking into a home once every 8 years; this conclusion has been cited by politicians, police, and criminologists to argue that more police on the beat is not the answer to crime on the street. Yet Clarke and Hough's analysis was based on limited notions of crime being informally distributed, on a homogenization of 1980s London crime data only, and on the belief that all police foot-patrol officers police all neighborhoods as randomly strolling automata. Despite the basis of these calculations, research by John Burrows and his colleagues demonstrated also that random, as opposed to directed, beat patrolling is ineffective. This limited research has been used to make a case for the need for others to work in partnership with the police to reduce crime strategically by focusing on reducing opportunities for offending by altering the physical environments where crimes take place.

Around the same time that it was becoming accepted that the police alone were not the answer to various crimes, Clarke's Crime as Opportunity, Situational Crime Prevention Approach (SCP) was promoted throughout the Home Office as the answer to "here and now"—rather than the distant future—specific crime problems in specific places. SCP was then, and remains today, the policy makers' problem-oriented "administrative criminology" salve to Robert Martinson's profoundly negative conclusion that "nothing works" in tackling crime by seeking to rehabilitate offenders.

In 1993, the U.K. Home Office implemented the Five Towns Programme, which shaped Safer Cities. Five Towns aimed to test the multiagency

partnership approach to crime reduction by supporting the role of the police through SCP, and to a lesser extent, “social development” initiatives were tested also.

As A. M. Liddle and A. E. Bottoms note, Five Towns was conceived after an interdepartmental “circular” in 1984, which identified a series of “needs” for communities to support crime reduction through multiagency collaboration and bespoke schemes to tackle unique local crime problems.

The Home Office met the salary costs of coordinators in the following five towns in England and one in Wales: Bolton, North Tyneside, Croydon, Wellingborough, and Swansea. The Home Office levered-in funding from other central government departments and local government sources, which included the Department of the Environment, Department for Education and Science, and Croydon Borough Council.

Satisfied that the Five Towns study proved the approach could work, Safer Cities was launched to target places with high levels of recorded crime and deprivation. Phase 1 began in 1988 and ran for 7 years, covering 20 cities and boroughs in England and Wales. Funding for phase 1 ended in December 1993. Phase 2 was funded by the Department of the Environment, Transport and Regions, beginning in 1994 and ending in 1998.

What Safer Cities Set Out to Do and How

In each project area, coordinators were employed directly or seconded from police, local government, probation, and other related services. Early Home Office directions to coordinators stated that they must be observed by the local community to have timely successes, because gaining local confidence would help to ensure future cooperation from the community. From that cause, in the first 2 years, more than 70% of the budget was spent on situational initiatives, such as locks and bolts, alarms, fences, and closed-circuit television (CCTV).

But this did not last. Research by Mike Sutton found that within 4 years, spending had shifted significantly from SCP toward socially oriented, secondary crime prevention offender schemes, so that by 1992–1993, slightly more than 50% of schemes were situational in nature.

The shift toward offender-oriented program activity that began in phase 1 continued in phase 2.

In 29 new project areas covered in phase 2, some three fifths of the 1,400 schemes were designed to reduce long-term, rather than immediate, situational offending.

Whereas slightly more than half of schemes in phase 1 employed SCP methods, in the last years of phase 2, only around a third of schemes were focused on reducing immediate opportunities for crime.

In phase 1, all 20 project areas were managed top down through Home Office civil servants guiding locally based project coordinators—who in turn operated with reference to locally appointed steering committees. Approval for expenditure and project management was ultimately the responsibility of Home Office civil servants.

The program was managed differently in phase 2 when the government appointed managers from not-for-profit organizations Crime Concern, the National Association for the Care and Resettlement of Offenders, and the Society of Voluntary Associates to monitor expenditure and maintain central management.

Impacts and Evaluation

Despite extremely limited evaluation of the success of Safer Cities, the Home Office promoted the partnership approach as the way forward in the hugely influential report: “Partnership in Crime Prevention.” This approach was seized on by the Standing Conference on Crime Prevention, chaired by James Morgan, which in turn produced the Home Office report “Safer Communities: The Local Delivery of Crime Prevention Through the Partnership Approach.” This report became renowned and is now known simply as the Morgan Report.

The Morgan Report recommended that local authorities should work in conjunction with the police and have a statutory responsibility for developing and implementing community safety and crime-prevention programs. However, despite the best efforts of Home Office civil servants, Thatcher’s conservative government was adamant that for political party reasons, local authorities would have their powers curtailed rather than enhanced. It was not until New Labor won the general election in 1997 that new ministers and the Home Secretary found a ready-made policy to claim as their own. New Labor implemented the Morgan

Report's key recommendation by way of Section 17 of the Crime and Disorder Act of 1998.

And so it was that the multiagency approach to crime reduction was made compulsory by law in Britain even though the dream of the advantages and efficiency of the multiagency approach over unitary authority practice was seriously questioned at the time by research into the Safer Cities Program, which was conducted by many academics, such as Reese Walters and M. Sutton. That said, various schemes within the Safer Cities program were evaluated and found promising. Nick Tilley in particular published important findings on the benefits and limitations of schemes to protect small businesses and on early use of CCTV to reduce car crime.

Implementation Issues

The Home Office promoted multiagency partnerships as an efficient way to reduce crime. However, simultaneously, it was obliged to publish independent research by Tilley and Liddle and by Loraine Gelsthorpe, which revealed the great tensions and difficulties that co-coordinators and their crime-reduction partners were experiencing in implementing the practice of both multiagency partnership working and systematic problem-oriented crime reduction. These findings were supported by later research by Sutton revealing several conflicts between agencies as well as the fact that half of the multiagency Safer Cities steering committees in phase 1 were described by their own co-coordinators as either weak or "just a rubber stamp" for the coordinator's own wishes.

The Way Forward

The Safer Cities Program was a groundbreaking demonstration project, implemented because significant moves were being made in the U.K. government policy arena toward tackling crime with measures aimed at reduction through thwarting and reducing the opportunities to victimize that facilitated crime.

With Safer Cities, the U.K. government was responding to a pervading view in the late 1970s and throughout the 1980s that tackling crime could not be left to the police alone.

Community safety is at the time of writing a major U.K. government priority and has been

emphasized in programs such as the Single Regeneration Budget and the Crime and Disorder Act of 1998. The problem-solving approach to crime that was tested with Safer Cities is an intuitively, compellingly sensible notion, with statistically significant and attributable reductions to burglary rates achieved in phase 1. However, despite the Safer Cities experiment, whether partnership working in crime reduction is measurably superior to unitary models of practice remains completely unknown.

Crucial lessons from Five Towns and phase 1 of Safer Cities did not adequately inform phase 2. Lessons and warnings from Liddle and Bottoms, from Sutton, and from Eckblom et al. were all unheeded. The official line in phase 2 of Safer Cities was one of "hands-off" from the civil service, despite the U.K. government's earlier research findings that local co-coordinators left to their own devices tended to rely on poorly worked out strategies and implemented schemes according to intuition rather than "knowledge" of what works or is promising in reducing crime. The Department of Communities and Local Government's retrospective review concluded that Safer Cities in phase 2 was characterized by the same earlier problems of poor monitoring and loose central direction.

If there is one core criminological lesson to come out of the Safer Cities experiment, it is that the U.K. government needs to ensure that its current community safety partnerships are not perpetually repeating the mistakes of the past. Just as quackery in medicine is unacceptable, so should it be with crime reduction.

SAFETY PLANNING FOR ABUSED CHILDREN

Child maltreatment is criminal behavior that includes physical abuse, sexual abuse, neglect, and emotional and/or psychological abuse. The magnitude and prevalence of child maltreatment within the United States is difficult to determine, as no single system captures all forms of known maltreatment across various agencies that investigate

abuse and neglect. The Uniform Crime Reporting (UCR) Program, the National Incident-Based Reporting System, and the National Crime Victimization Survey do not capture statistics specific to child maltreatment. Rather, the most widely used indicator of child victimization is the National Child Abuse and Neglect Data System (NCANDS), which is a voluntary national data collection system that measures and tracks child maltreatment investigated by state Child Protective Service agencies. NCANDS estimates nearly 3.3 million reported allegations of child abuse and neglect to Child Protective Services agencies, which involve approximately 6 million children. Of these allegations, nearly 30% of investigations are substantiated. Neglect has continuously been shown to be the most common form of child maltreatment nationwide; yet, it is the form of maltreatment least likely to receive criminal justice attention.

The frequency of child maltreatment nationwide and the impact that abuse and neglect can have on the child, not only during childhood but also in his or her later life, makes prevention programs that target child safety paramount. The need for prevention programs targeting the safety of children is apparent when examining the trends of child abuse, neglect, and child fatalities nationwide. For example, in 2001, 1.81 children per 100,000 in the U.S. population died as a result of abuse or neglect. In 2003, an estimated 1,500 fatalities were confirmed by Child Protection Service agencies. Of the total fatalities, 78.7% of the children were younger than the age of 4 years and 43.6% were younger than the age of 1 year. Responding to child maltreatment is an ever-evolving process. This entry explores the issues involved in addressing the needs of and safety planning for maltreated children, which include historical perspectives, need for prevention, causes of child maltreatment, and response and prevention programs.

Historical Perspectives

Maltreatment of children has historically not required government intervention; rather, abuse and neglect of children was commonly accepted within the rights of the family. Legal sanctions against perpetrators of child maltreatment is a relatively new concept within the United States, which makes a historical analysis of crime trends

difficult. Loose systems of child protection existed throughout the centuries; however, prior to the Industrial Revolution, established governmental responses to maltreated children within the United States were absent.

Historically, greater community concern was often placed on orphaned children, who were visible on the streets, than those who were maltreated within their own homes. The separation between the public and private realm was expected and how parents chose to deal with their children was largely viewed as a personal matter. The community was reluctant to intervene because of strong beliefs in preserving the sanctity of the family. Regardless, some individuals recognized that there were apparent problems with the way in which some dependent children were being treated. The view that the “best interest of the child” may at times outweigh family preservation began a shift in the way dependent children were perceived.

The New York Society for the Prevention of Cruelty to Children (NYSPCC), which was created in 1875, was the first agency to enforce children’s rights. The NYSPCC sought to rescue children from parental and adult cruelty and is recognized as the first national child protection agency, as well as the first agency known to work collaboratively with law enforcement and the court. Their work resulted in increased penalties for child abuse and amplified public support for these sanctions. The United States Children’s Bureau was founded in 1912 as a direct result of the perceived national need, largely stemming from the work of the NYSPCC, for child welfare programming in the country. The Bureau was responsible for investigating all reports that pertained to the well-being of children throughout the nation. The creation of and subsequent investigations by the Bureau resulted in government-run child welfare agencies.

During this time, interventions into families suspected of child maltreatment were considered generally acceptable. Although acceptance of intervention by social service agencies has increased, the criminalization of parental discipline and neglect of children’s needs has been and continues to be minimal. This observation indicates a possible lack of public consciousness toward the effects of maltreatment on children. Lack of concern for the impact of abuse on children results in lack of demand for law enforcement or judicial involvement. Child abuse reporting

laws, which were passed in all states by the 1960s, and the Child Abuse Prevention and Treatment Act of 1974, which mandated certain professions to report suspected maltreatment, have increased law enforcement involvement in investigations of child maltreatment. Although child abuse and neglect can be criminally prosecuted, the belief that parents have the right to punish their children, combined with demands for family autonomy, continue throughout society.

Every state currently has social welfare agencies responsible for investigating and responding to reports of suspected child maltreatment. Allegations of suspected child abuse and neglect are brought to these agencies through community members, many of whom are mandatory reporters. Under the Child Abuse Prevention and Treatment Act, every state requires certain professionals and institutions to report suspected child abuse and neglect. Those who qualify as mandatory reporters vary but typically include health care providers, teachers and school employees, social workers, counselors, day care providers, and law enforcement. These reports are made to mandated toll-free child abuse reporting lines. It is the dispatchers from these reporting lines who determine whether the reported concern rises to the level of a perceived safety threat to the child. It is this decision that results in investigations of child maltreatment within the home.

Need for Prevention

The literature indicates that the age range where parental-child bonds are formed is age 3 and younger. Maltreatment during these years likely results in the continuance of abuse and neglect throughout the child’s life. Children aged 3 and younger are most susceptible to violence and neglect by their caregivers in part because of the stress that can be intensified while raising young children. The use of prevention programs for new parents is not innovative, as most European countries have been using such programs since the early 19th century. Nations with such programs make them available to all families with new children to provide home visitation and assistance during a child’s early years. The closest nationally funded prevention program within the United States is the Special Supplemental Nutritional Program for Women, Infants, and Children (WIC). WIC provides its clients nutritional

education, food, maltreatment risk screenings and referrals to other social service agencies. However, WIC does not provide intensive or in-home services, and those who qualify for their services must meet income criteria, which means this program is not applicable to all who may benefit from its services.

Causes of Child Maltreatment

Prevention programs targeting safety of children strive to reduce the likelihood of child maltreatment within at-risk families. If it is possible to predict future injurious behaviors of parents towards their children and to provide supportive interventions, it is likely that the magnitude of the problem could decrease. The ability to identify families at risk for maltreatment can increase the effectiveness of interventions and result in the safety of more children. Prevention programs must have an understanding of what causes the behavior. This understanding subsequently assists practitioners, researchers and policy makers to assess more accurately who is truly at risk and to design programs to address their particular needs.

The research shows many factors prevalent within homes where children's safety is jeopardized. Consistent variables within the home and family include abuse of a previous child within the home; parental psychiatric disorders or mental retardation; serious health problems during pregnancy; young age; low educational level; unemployment; low income; substance abuse; domestic violence within a relationship; history of abuse in parent's own childhood; lack of adequate housing, food, or medical care; little familiar or social supports; and lack of involvement by a second parent. The existence of any one of these predictors does not identify a family as "at risk." Rather, composite scales and measurements have been created to assess the level of risk using these predictors within each individual situation.

Among the used and accepted measures of risk of child maltreatment are the Family Functioning Scale, Family Problem Checklist, Child Abuse Potential Inventory, Hawaii Risk Indicators Checklist, Kempe Family Stress Inventory, Bayley Scales for Mental and Motor Development, and Parent Readiness and Risk Assessment. These instruments have been examined and tested repeatedly for their reliability in measuring potential for

child maltreatment. Through the use of these measurements, research has identified trends within families where the safety of the children is in question. The use of these scales shows that common characteristics are found within families who have substantiated child maltreatment within their homes and those identified as at risk for maltreatment.

Response and Prevention

Many risk indicators of child abuse and neglect are not found only in homes with child maltreatment. Unemployment, lack of adequate housing, and lack of social supports are not causally related to child maltreatment. Rather, these intervening influences can arguably increase stress within the households, which can lead to safety concerns for children. Prevention programs should focus not only on the safety of the children but also on these community factors that parents may be unable to change on their own. Prevention programs that focus only on child safety, while ignoring issues such as community disorganization, lack of social supports, and unemployability, may be less effective than those that consider what the research shows influences a family's propensity toward child abuse and neglect.

The magnitude of child maltreatment within America's homes cannot be ignored. The statistics report that nearly four children every day die at the hands of their parents, which reinforces the need for prevention programs. Raising children can be an incredibly stressful situation, especially when it is combined with financial, relationship, and substance abuse problems. As a society, recognizing stresses within homes and implementing programs with this understanding is likely to reduce stigma of participation within such programs and possibly increase parent's willingness to ask for help. Only through the acceptance of the enormity of child abuse and neglect combined with implementation and methodologically rigorous evaluations of prevention and intervention programs can there be any hope that the problem can be addressed successfully.

SAFETY PLANNING FOR BATTERED WOMEN

The harsh experience of violence against women can be witnessed in the face of its victims and measured in prevalence rates, underscoring that no woman stands immune from this form of victimization. Not only is the shadow cast by gendered violence long, but also the impact on a woman's health and mental health can be profoundly negative and enduring. Violence against women, particularly when perpetrated by an intimate partner, is associated with higher mortality rates, acute injury, and chronic illness in its victims. The 1998 National Violence Against Women Survey (NVAWS) reported that 41.5% of women physically assaulted and more than 36% of women sexually assaulted by an intimate reported injuries as a result of their most recent victimization; in a single year, half a million women sought medical treatment for their injuries. Studies in hospital emergency departments document that more than one third of women seeking emergency

medical care for violence-related injuries have been injured by a current or former spouse. Violence against women leaves its mark in bruising and broken bones, and every year, thousands of women ultimately lose their lives to violence from an intimate partner. In fact, homicide is one of the leading causes of premature death for women in the United States.

The widespread nature of violence and the severity of its impact give compelling reason for criminal justice, health, and mental health professionals to attend to the reduction of risk for women and their families. Strategic safety planning is an important tool to help survivors of intimate partner violence achieve that risk reduction and live lives with improved safety. In the largest femicide study conducted to date, almost half of the murder victims had been observed in the criminal justice or mental health system during the year before their deaths. The message here is not only that danger is inherent in cases of intimate partner violence but also that professionals have an opportunity to prevent homicide if they attend to that risk.

Risk, Lethality, and Reassault

General Risk of Intimate Partner Violence

The assessment of risk is fundamental to safety planning, but more than one construct is important to the process (see Figure 1). First, although no woman is immune from victimization, the general risk of exposure to intimate partner violence is not the same across populations of women. For example, minority women, women who live in poverty, and women with severe mental illness may experience higher rates of violence. An elevated risk of exposure to certain forms of intimate partner violence may also be experienced by younger women. Research shows that battered women are at higher risk of sexual violence than the general population and that incidence rates among battered women in shelter samples are even higher. The implication of the general risk construct for professionals addressing safety is that universal screening for violence among all populations of women observed in health, mental health, and criminal justice settings is important and a particular focus on subpopulations of women may be warranted.

Figure 1 Risk, lethality, and reassault

Lethality Risk

At a practical level, knowing which cases of violence will expose a victim and her children to the greatest degree of harm is fundamental to safety planning. “Lethality risk” can be defined as measuring not just who is at risk but also what kinds of cases are associated with the most danger. Studies of homicide of women give clues to which cases may pose greater risk, and the results suggest that the presence of such factors as the offender’s access to a gun, previous threats with a weapon, having the offender’s stepchild in the home, and physical estrangement or separation should give cause for concern. The abuse types experienced by the victim may also shed light on the risk level, as stalking, forced sex, and abuse of the victim during her pregnancy have all been identified as key markers of victim risk. Importantly, within some of these risk factors are indicators of both increased risk of physical harm as well as increased risk of homicide. For example, research finds that victims of intimate partner violence whose abuse includes rape by their partner will sustain greater physical injury than women raped by nonintimates; partner rape and rape during pregnancy have been identified as a risk marker in femicide research.

Studies on offenders also provide valuable insights into lethality risk. For example, research

suggests that generally, violent offenders whose abuse is indiscriminant with respect to victim rather than being limited to an intimate partner pose a greater threat. Offenders with impulsive or angry dispositional traits have also been found to pose an elevated risk. Clinical features of the offender may also be telling, as studies find that substance abusing offenders, those who are jealous and obsessive, and those whose levels of depression are indicative of suicidality may also be more lethal to the women in their intimate lives.

Risk of Reassault

Studies find that more than two thirds of victims of intimate partner–related homicide were previously abused by the partners who killed them. As a result, the third construct central to safety planning is the risk of reassault, that is, the ability to identify contextual or situational factors that can assist in predicting when a woman’s risk will escalate and violence reoccur. Historic factors, such as prior abuse, and contextual factors, such as separation, are two chief risk markers.

Among the contextual factors most salient to the risk of reassault is that of separation or estrangement of the intimate couple. Research has long made clear that batterers do not cease violence on the victim’s departure, and in fact, criminal justice data show that the rate of intimate-offender attacks on women separated from their partners is about 3 times higher than that of divorced women and about 25 times higher than that of married women. Studies of women housed in battered women’s shelters find that fully one third have been physically assaulted during their separation from the offender, and research finds separation-associated stalking and psychological abuse as well. Similarly, studies of intimate partner homicide show that the murder is frequently preceded by a history of physical and other domestic abuse and often involve a recent attempt at or completion of separation by the victim.

Familiarity with the three constructs of risk, lethality, and reassault are central to laying the groundwork for the step-by-step planning that becomes the focus of strategic safety planning with victims.

What Is Strategic Safety Planning?

Strategic safety planning involves a crisis-oriented approach, informed by the presence of risk factors that focus attention on both achieving and maintaining safety for the victim of intimate partner violence and her children. It is not a singular or one-time event; rather, it is an ongoing process that adapts as contextual and clinical factors associated with the women's situation change and the danger potential increases or decreases (e.g., contextual factors such as the offender's loss of a job, initiation of stalking the victim, or his increase in alcohol consumption; or clinical factors, such as his growing depression or the beginning of suicide ideation, would necessitate changes in the safety plan).

Safety planning also cannot be confined to just the logistics of physically separating from the violent partner. Separating from an abusive partner is an important option for a victim, but it may not be the one she views as safe or viable at the time the safety plan is being drawn. It is critical to remember that leaving does not automatically stop violence (and, in fact, it can be associated with its escalation), so professionals should not force that goal on the survivor with whom they are creating a safety plan.

Strategic safety planning should be understood for the complex process it is: Risk assessment measures more than one thing (i.e., both lethality and reassault), and it is measuring a level of risk that is influenced by multiple variables (historic, clinical, dispositional, and contextual factors). Additionally, strategic safety planning is not just a tool for professionals to use or provide to their clients; rather, it is a dynamic partnership that professionals and survivors enter into as a way to achieve and maintain greater safety.

Stages of Strategic Safety Planning

Step 1: Risk Appraisal

The first step in organizing a strategic safety plan necessarily starts with a process of identifying cues that risk exists or is increasing in the victim's environment. This process involves scanning the environment, evaluating the offender's behavior or noticing key changes in what he does or says, and recognizing threatening circumstances. This risk appraisal process is unique to every victim, as

personal history and the immediate context of the violence means the same behavior that is threatening to one woman will not attach that same meaning to another.

The risk appraisal process also changes over time as a woman's experience with the offender teaches her to associate certain actions or cues with subsequent violent behavior (e.g., when he drinks or becomes more depressed, that is most often when the abuse occurs). Victims and survivors may also learn more subtle cues over time, such that a glance or a nondescript behavior that is unnoticeable to another person conveys significant threat to her. A change in the appraisal process may also occur during a woman's pregnancy or when she has children in the home. What a victim can tolerate for herself in the way of threat may not be tolerable if it seems to expose her children to a risk of harm.

This more sophisticated understanding of the offender's behavior and its meaning is critical to the effectiveness of safety planning. This means that the victim herself serves as the greatest source of expertise to the safety planning process. Women who have suffered repeated exposure to violence are best positioned to understand the offender's behavior in the context of their relationship and prior history and to identify the subtle cues to heightened risk. Ironically, however, the very experience that creates the expertise to assess risk can also impair a victim's intuitiveness. This is particularly true for women who have been exposed to egregious psychological abuse, which robs a woman of her ability to appraise cognitively her relationship to the world. Risk assessment skill on the part of the victim can also be hindered by her use of alcohol or drugs and by the long-term effects of trauma exposure and related psychological distress reactions.

Step 2: Identification of Resources and Protective Factors

The second step in the safety planning process focuses on what can be done. It is the process by which victims contemplate their options in light of elevated risk and begin decision making regarding concrete steps that should be taken. As in the case of primary appraisal, the victim's perspective is imperative. Not only does she need to identify the

cues or “red flags” of risk, it is her appraisal of the consequences of taking any remedial actions that will have the greatest impact on what steps she takes. If she does not perceive herself as worth saving or that available resources are viable or safe, she may be stymied from action. For some women, for example, experience has taught them that contacting law enforcement will bring swift and lethal retribution from an abusive partner. In that case, knowledge of how to contact 911 is not useful because she perceives that police protection is not a viable safety resource.

The safety planning process includes identification of concrete steps that can be taken or implemented by a woman and her children. Tangible, specific steps that women are encouraged to take include the following:

- Practice quick exits from the shared residence with the abusive partner.
- Have children participate in the safety plan, which includes teaching them how to telephone police and fire departments. This can also include setting up a code word or signal for children or friends or both so they will know that the situation has become dangerous.
- Keep car keys near the door or in a location where they can be readily accessed and keep an extra set of keys hidden.
- Hide a purse with extra cash and sources of identification.
- Store important documents in a safe place, which include birth certificates and social security numbers.
- Keep a suitcase packed and stored in a safe place at home or at a friend’s home.
- Keep an accessible list of important telephone numbers to call, including police and fire departments, battered women’s shelters, mental health crisis lines, and numbers for professionals assisting on her case including attorneys, victims advocates, therapists, physicians, or others.
- Know how to access Internet safety resources in a safe, nontraceable way.
- Have ready access to copies of civil orders of protection or court orders related to the case.

It is important to include in the risk appraisal and strategic planning processes the consideration of the victim’s mental health status. Long-standing

abusive relationships can take a psychological toll, and if left unattended, these effects may diminish the internal resources she needs to achieve and maintain safety. Tracking her levels of depression or substance abuse may be important parts to reducing suicide risk and keeping her maximally capable of protecting herself and her children.

Strategic safety planning, in a real way, is a means to end intimate partner violence, one woman at a time.

SAME-SEX INTIMATE PARTNER VIOLENCE

Since the early 1980s, a growing body of research has revealed that violence within gay and lesbian relationships exists and is fairly well documented. According to the National Coalition of

Anti-Violence Programs, in 2001, reported cases of interpersonal violence increased 25% in the gay and lesbian community, reaching a total of 5,046 cases. The term *domestic violence* is still used, but in academic and professional arenas, it has been replaced by *intimate partner violence*, which is a more inclusive term and more appropriately captures the dynamics and types of abusive relationships. Abuse in homosexual relationships is typically overlooked, especially in terms of theoretical scope because they explain domestic violence, theoretically, as a gender-based phenomenon: a form of male oppression of women. Consequently, same-sex intimate violence typically is not constructed as a social problem. Same-sex relationships do not enjoy the legitimacy given to heterosexual couples, thereby making it nearly impossible to recognize abuse among same-sex couples.

Without recognition of the abuse in the scholarly and popular literature and among legal and criminal justice professionals, the problem remains unaddressed, and survivors' needs for assistance go ignored. This entry explores the definition of domestic violence and battering as it applies specifically to same-sex couples, includes a brief discussion of the historical background of the issue, provides information prevalence and incidences of same-sex domestic violence, and addresses some examples of barriers gays and lesbians face when seeking intervention assistance.

Background and Significance of the Problem

The significance of this issue as it relates to the field of criminal justice lies with the fact that the prevailing assumption in society centers on the notion that intimate partner violence involves men who beat their wives or girlfriends. The background concerning the dearth of knowledge surrounding same-sex domestic violence begins with a brief look at the social and historical context within which the battered women's movement and feminist theories of domestic violence emerged. Prior to the battered women's movement of the 1970s, existing research and theories diminished domestic violence as a crime and typically blamed the victims. In the late 1960s, activists began to politicize the predicament of the battered woman. At that time, the police usually would not assist

victims of domestic violence even though such violence was illegal.

During the 1970s, the battered women's movement defined and recognized the different types of violence and the elevated probability of repeated abuse that is reflected in the cycles of violence unique to partner abuse. The battered women's movement also challenged the current legislation at this time and encouraged states to offer protections to victims in the form of civil protection orders, to create shelters and other services, and to enhance penalties under the criminal law. Unfortunately, many of these achievements failed to benefit gay men and lesbians.

Prevalence and Incidence Research

Recent decades have witnessed a plethora of research on the *prevalence* of intimate partner violence among same-sex couples, which shows that prevalence rates among same-sex couples are comparable with abusive heterosexual relationships for physical and sexual abuse. However, prevalence information that is gathered and reported remains somewhat speculative because of the subjective characteristics of the research methodology employed in a particular study. Moreover, it is, at times, not clear whether the incidence or lifetime prevalence rates are being reported. However, one recent nationally representative sample found the lifetime prevalence of same-sex intimate partner violence was approximately 11.4% versus 20.3% for heterosexual couple violence. One commonly cited set of statistics, however, indicates that the prevalence of domestic violence among gay and lesbian couples is approximately 25% to 33%, which is very similar to that of heterosexual couples.

Reported crimes reflect *incidence rates*, so they are expected to be lower than prevalence numbers. Tabulations of reported crimes depend on several actors, which include the victim's or someone's decision to report the crime to law enforcement. Consequently, incidence rates usually underestimate intimate partner violence. The most significant difference between heterosexual and same-sex intimate partner violence is the fact that same-sex batterers have the additional weapon: the threat of "outing" their partner to family, friends, employers, or community. For example, in terms of lesbian relationships, abuse may be of the physical,

sexual, verbal, emotional, and psychological variety. Common forms of physical abuse include pushing and shoving; hitting with fists open or closed; scratching or biting the face, breasts, or genitals; and throwing things at the victim/survivor. Gay and bisexual men suffer similar forms of abuse, which include kicking and driving recklessly with another passenger in the car. In terms of sexual abuse, in a study of sexual coercion among lesbian and gay college students, researchers found that 31% of lesbians had been sexually abused by other lesbians.

Research on verbal abuse among same-sex couples has been as high as 95% in some studies. Common forms of verbal threats are outing the victim to family members and friends, being demeaned in front of others, having sleeping or eating habits interrupted, and being treated like children or pets. Emotional and psychological abuse also takes the form of restricting the victim's movements, lying to the victim, and harassing the victim. Other forms of reported abuse include financial abuse, where one partner establishes control over the finances or fails to contribute to expenses, and destruction of the victim's property. In general, the research shows that lesbian and gay victims experience shame, anger, isolation, low self-esteem, and confusion as a result of the abuse they experienced.

Barriers to Reporting Battering Incidents

Many barriers exist for homosexual victims of intimate partner abuse. Some of these barriers are similar to those experienced by heterosexual victims, but a few are unique to homosexual victims. These barriers include the victim's fears of reprisals, the victim's desire to move "ahead" and get on with his or her life, the belief that no good can come from reporting the incident, and the sense that the local homosexual organization caters or helps other kinds of individuals who do not have the same sexual orientation as the victim. Additional barriers exist to homosexual victims who wish to report their battering experiences to the police. For example, common barriers include feelings of personal shame, fear of reprisal, fear of being "outed," fear of being mistreated by the police, and the supposition that nothing will be done to help them. Moreover, victims often presume that the offender,

even if arrested, will "get away" with the crime because they believe that restraining orders will not work. Last, homosexual victims often possess a fear of being harassed by the police and a fear of being arrested oneself, if the police assume that mutual battering has occurred.

Because of these barriers, either perceived or actual, some shelters have implemented a separate screening for lesbian victims of abuse. Separate screening justifications include the fact that a lesbian batterer might drop by to observe whether her partner was attending the group; a lesbian victim might feel uncomfortable talking about her female counterpart in a group of heterosexual females; and last, a lesbian might not go to the shelter unless she feels it is free of homophobia.

Additionally, many social and legal barriers exist, which prevent these victims/survivors from dealing appropriately with this problem. Often, the gay and lesbian community itself lacks awareness or may attempt to cover up the existence of domestic violence and sexual assault for fear of additional social stigmatism, which may bolster anti-gay sentiment and perpetuate the belief that homosexuals cannot have a violence-free relationship. Although more aggressive police tactics, like mandatory arrest, have emerged in the past 25 years or so, victims in both types of relationships do not get sufficient assistance from the police.

These insufficiencies are more pronounced in gay and lesbian abuse situations. For example, in some states, there have been negative judicial decisions made toward gays and lesbians, especially those that deal with children and parental rights. Furthermore, misjudgments are frequently made about the size of the aggressor. The perception is that the person who is physically larger must be the batterer, but this is not always the case. Therefore, with the prevalence of abuse at epidemic levels, the question of whether quality services are available that serve the needs of survivors must be asked.

Nonetheless, with support and a focus on victim empowerment, advocates and other supporters can assist homosexual victims through the process. These advocates and supporters should become part of a support network and act as a referral source. Intimate partner violence is violence that knows no barriers, so no one is immune. What is critical is that homosexual victims receive the same

level of support as heterosexual victims. Only with a widespread cultural transformation will these barriers crumble.

SCANNING, ANALYSIS, RESPONSE, AND ASSESSMENT (SARA)

The acronym SARA has almost become synonymous with problem-oriented policing. In short, SARA describes the four elements that are part of a problem-oriented policing project, namely scanning, analysis, response, and assessment.

The fundamental idea of problem-oriented policing—to get away from reactive incidence-driven policing and conducting police business in a far more analytical way, with a strong emphasis on

prevention—was described by Herman Goldstein in 1979. It was immediately received with great interest among the police and by organizations responsible for the police function like the Home Office in the United Kingdom. Police forces both in the United States and United Kingdom soon started to put it to practice. It is in what best can be described as field tests that the acronym first appears. John Eck and William Spelman reported several cases where the philosophy was practiced, and they summarized the four essential steps of a problem-oriented project with the help of the SARA acronym.

The starting point for problem-oriented policing is a *problem*. In the context of problem-oriented policing, problems are defined as (1) a cluster of similar, related, or recurring incidents rather than a single incident and (2) substantive community concerns. A problem might appear on the agenda for many reasons. It might be something that “always” has existed, or it could be a new form of crime or one that has increased. It might come to attention through mass media, by a citizen group, or by a newly appointed officer or chief of police. Often, the initial definition and understanding is superficial and sometimes wrong.

In the *scanning* phase, the problem is defined, and vital aspects of it are considered. An important dimension is the harm it causes. Basic questions to be answered are as follows: Where do the events that constitute the problem occur, how often, and at what times? Scanning often starts by an examination of crime statistics or call for service data. It is extremely important to be specific. For instance, exactly what type of robbery, assault, or car crime comprises the problem? Sometimes, many different sources of information that takes different methods to collect are needed to conduct the scanning. It might be necessary to make interviews, surveys, or observations to get a full picture of the problem. Already in the scanning phase, considerations must be made for collection of preintervention data for the assessment.

The purpose of the *analysis* is ultimately to identify causes or preconditions open to manipulation, which are likely to affect the problem. It is, of course, helpful to find out what is known about the problem type in question from other sources. Part of the analysis is to look at the way the problem has been addressed and the consequences of it. To carry out a complete analysis of causes is an

extremely demanding task that, however, is unnecessary in this context. It is sufficient to find factors that can be changed or manipulated—the so-called pinch-points, which means to focus on immediate causes, usually of a situational nature. Making a clear distinction between scanning and analysis can be difficult, because an inspection of data obtained in the scanning phase often automatically turns into the analysis.

Response refers to the search for tailor-made solutions to remove the causes of the problems and then to implement the selected responses. It thus consists of two clearly distinguishable steps: (1) finding out preventive measures and (2) getting them implemented. The choice of response also requires an analytical, creative approach. In addition, it is essential at this stage to have access to knowledge about methods that have been used successfully elsewhere when similar problems have been encountered. Measures should not be too ambitious nor expensive, preferably sustainable, and close to the identified causes, where it is easy to observe the relationship between the measure and its intended effect. Both steps in the response phase are built on what is accomplished in the scanning and analysis phases, and it should ideally provide a convincing case to be presented to those in a position to act and change the contributing factors—the problem owners (or solution owners as they sometimes are called). Their reaction varies, where they sometimes are easily persuaded to implement the suggested measures, and sometimes hard or even impossible to persuade. In the latter cases, levers may have to be used. A rule of thumb is that the more coercive the levers, the more solid the case to present must be.

Finally, in the *assessment* phase, the degree to which measures are implemented as planned is explored and the effectiveness of them is evaluated. Sometimes, a process evaluation is unnecessary, because it was evident in the response phase that the measures were implemented. The impact evaluation is conducted to discover whether the expected effects have come about and whether side effects have occurred. An example of a side effect is crime displacement, where crimes, for instance, are committed at another place. It is important to establish whether displacement, if it occurs, is malign or benign. Malign means that the problem altogether worsened, and benign means that it improved. An example of a positive side effect is the diffusion of

benefits. Crime also decreases in areas or for objects not directly affected by the measures. Evaluation is a demanding task that entails both data collection and rigorous analysis. In a problem-policing project, the impact evaluation will most often be comprised of the “one-group pretest-posttest” design. It is a weak design and is low on internal validity. But for local, often small-scale, interventions of this kind, it is sufficient to show that the problem decreased, and that if so, it can be attributed to the implemented measures.

It can be misleading to perceive the process from problem identification to evaluation of effectiveness as following a predetermined sequence where analysis only takes place in the second phase. In fact, the process is iterative with analysis going back and forth between the stages. For example, new information gained during the assessment may require fresh analysis.

The philosophy of problem-oriented policing and the SARA process are intuitive and immediately attractive. Experience shows, however, that it is easy to underestimate the complexity of carrying out proper problem-oriented projects. In fact, several examinations have shown that implementation often is weak and that the quality of problem-oriented policing projects, judged by academic criteria, frequently is poor.

Admittedly, SARA has its weaknesses and simplifies a complex process. Some have tried to put forward other frameworks that more in detail reflect the processes going on in a problem-oriented project. However, the SARA model has proven to be robust and is thoroughly established. It is a key concept in both the Herman Goldstein and the Nick Tilley Awards, where projects and submissions are expected to adhere strictly to the SARA form. It is also used extensively in the material made available by the Center for Problem-Oriented Policing Web site, where, for instance, three types of guides more or less are modeled according to the SARA principles. There are (1) problem-specific guides, (2) response, and (3) tool guides, all of which are produced to support problem-oriented policing.

Even if there has been a strong and positive development in problem-oriented policing, there is still a potential for improvement. The SARA model is actually an action research model. To stick to it meticulously takes a competence rarely found in the police organization. Goldstein has repeatedly pointed

out that to improve policing cooperation between police and academia must be intensified. Here is the challenge, both for the police and for universities and other institutions of higher education.

SCHOOL-BASED BULLYING PREVENTION

Bullying is one of the most pervasive forms of juvenile misbehavior often constituting delinquency and sometimes crime. Although acts intended to ridicule and intimidate others have historically

been largely ignored and considered a fairly normative aspect of child and adolescent social development, bullying has emerged during the last 20 years as a serious social problem. Bullying is now widely considered in social science and education contexts as far more than a peccadillo but rather as an emergent form of delinquency and a gateway to other antisocial and criminal behavior.

Acts of bullying may be executed so as to render physical and/or psychological harm with extreme incidents such as the highly publicized 2006 suicide of Megan Meier, a 13-year-old Missouri girl who was bullied via the Web site MySpace. Bullying is often stereotyped as a group event with a single victim. In reality, bullying is far from monolithic and assumes multiple forms that range from in-person encounters, gossip and slander, and telephonic harassment to cyber bullying. These acts may involve a single or multiple perpetrators and victims. Victims of bullying experience a range of injuries and harm, which include physical abuse, social ostracism, and various mental health issues, such as eating and sleeping disorders, anxiety, depression, and low self-esteem. Beyond Web-based communication formats (e.g., electronic mail, cell phone texting, chat rooms, and blogging), the cyber age enables the posting and manipulation of images, which makes bullying both multifaceted and unbounded by daily temporally ordered routines. Although addressing bullying is a pronounced social concern, generally, its origins and occurrence is heavily based on the physical locale and social dynamics of schools.

The bullying-school nexus is particularly problematic in that victims often simply avoid school because of the actual bullying or fear of bullying; thus, ironically, these individuals commit delinquency in the form of truancy. Truancy is one warning sign of possible bullying and assumes a dual reality with both victims and bullies engaging in higher levels of truancy than other students. Bullying is thus a serious matter beyond the direct and indirect harm associated with single events that worsens the school environment and is detrimental to educational attainment.

Prevalence of Bullying

Bullying, although receiving less attention than more publicized forms of delinquency such as

drugs and gangs that have prompted national programs (e.g., Drug Abuse Resistance Education [D.A.R.E.] and Gang Resistance Education and Training [G.R.E.A.T.]), is both a widespread and increasing social problem. Several studies have been conducted to assess the prevalence of bullying in schools, the most comprehensive of which was the World Health Organization's Health Behavior in School-Aged Children. This 2001 nationally representative survey of 15,686 students in grades 6 through 20 in public and private schools throughout the United States revealed bullying as a common feature of respondents' school experiences. Nearly one third (29.9%) of respondents reported moderate or frequent involvement in bullying. Of these, 13% indicated they had bullied another student, 10.6% reported being the victim of bullying, and 6.3% reported that they had both bullied others and been bullied. Results also suggested that males were more likely to bully and be bullied compared with females. Bullying is also more commonplace among younger students (grades 6–8) than older students (grades 9–10).

This study also indicated that bullying varies by demographics. Black students were less likely to report either bullying or being bullied, whereas Hispanics were slightly more likely to report greater involvement in moderate and frequent bullying of other students. Although differences were not observed in the frequency of being bullied across geographic location (i.e., urban, suburban, town, or rural), small differences did appear in the frequency of bullying others. Suburban youth reported less involvement in moderate bullying, whereas a greater percentage of rural youth reported bullying others.

A more recent study, the Health Resources and Services Administration's 2009 "Bullying among Children and Youth with Disabilities and Special Needs," also informs our understanding of bullying, generally, as well as calling attention to issues more common to special populations. Certain populations are at particular risk of being targeted by bullies. Recent research has suggested that children with learning disabilities and those with attention-deficit/hyperactivity disorder (ADHD) are more likely to be teased or physically bullied. Additionally, children with medical conditions that affect their appearance (e.g., cerebral palsy or muscular dystrophy) are also more likely to be targeted

by peers. Relatedly, obese children are more likely to be teased or made fun of because of their weight and to be socially excluded. Other targeted groups involve children who are diabetic and insulin dependent, as well as those who stutter. Bullying has been found to be particularly harsh for this latter group, with 83% of adults who had stuttering problems as children reported being teased or bullied; 71% of those who had been bullied reported that it happened at least once a week.

A recently identified at-risk group is gay youth. Gay youth deal with harassment, threats, and violence directed at them, often on a daily basis. These youth experience anti-gay slurs approximately 26 times per day or once every 14 minutes. Some data suggest that as much as one third of gay youth have been threatened or injured at school in the last year alone. As a result, gay students are more likely to skip school and ultimately drop out. In fact, 28% of gay students will drop out of school as a result of the constant stress associated with bullying, intimidation, and violence.

School-Based Programs: Prevention and Intervention

Studies of school-based bullying have generated findings that inform research-based best practices for prevention and intervention. The body of bullying research, especially program evaluations, equips school administrators and juvenile justice authorities with a "menu" of both proactive and response options. The most general of these options includes changing the school environment with emphasis on establishing, communicating, and reinforcing clear rules and shared values. Peer norming initiatives are a leading example of a shared values environmental change initiative. In addition to behavioral expectation strategies, school climate change strategies also include grouping students in various ways so as to realize smaller and less alienating in-school contexts.

Stronger administrative capacity (i.e., discipline-based rules enforcement) has proven successful in some school districts, especially when major discipline management-related variables (e.g., predictability of sanctions, clear behavioral norms, and consistency) are present. Other strategies, which seem promising but less supported by empirical evidence, include sensitivity programs for school

resource officers and the referral of bullying cases to teen or youth court.

A best-practices approach to bullying prevention and intervention necessitates the use of a multifaceted, holistic program that addresses the underlying antecedents of bullying. These approaches involve the many stakeholders who can assist in reducing bullying behavior, such as students, teachers, school administrators, and parents. The most frequently employed bullying prevention program was developed by Dan Olweus and is considered a “model program” by the Substance Abuse and Mental Health Services Administration (SAMHSA). The Olweus Bullying Prevention Program uses several mechanisms by which to address the problem, which include life and social skills training, family education sessions, peer resistance education, school change programs, behavior modification, counseling, in-school curricula, and parent training. Whereas the Olweus model has shaped the measurement and response to bullying nationwide, the survey questionnaire was pretested and refined in Europe, and its cultural relevancy in U.S. contexts has been assumed.

Public Policy and Legislation

Many state legislatures (e.g., Minnesota, Florida, and North Carolina) have proposed laws that require schools to have antibullying policies and programs, and more recently, a U.S. congressman proposed national legislation to address bullying. A particular focus of many of these bills has been to address new forms of cyber bullying. Despite this new legislative attention toward bullying, most schools in the nation already have disciplinary policies to deal with these types of behaviors. Moreover, the behavior referred to as bullying is typically addressed in existing school policies as well as possibly in criminal laws (e.g., fighting, threats, and intimidation). Schools have also implemented prevention and intervention programs, such as the Olweus program discussed above, to prevent and address this type of behavior.

Some have argued that addressing bullying behaviors is extremely difficult to do legislatively. As discussed above, many of these behaviors are already addressed in school policy and other laws, and thus the result may be legislation without

much impact. The seriousness with which policy makers debate this issue in the future, however, is apt to change as numerous high-profile 2009 bullying cases across the country have been featured in the national media.

SCHOOL-BASED THEORIES OF DELINQUENCY

School-based delinquency is a concern that transcends time and space. Because of compulsory education laws, young people are required to spend many of their waking moments throughout most of the year in school. Many offenders are youths. They are more likely to be involved in delinquent and criminal activity than older people, and they are more likely to be victims than older people. Schools and the pathways to school present myriad opportunities for delinquent acts, and they serve as a mechanism to prevent delinquency

in the community. This entry explores delinquency in the school environment and provides some of the common theoretical perspectives relating to delinquency in school, which include differential opportunities, strain, social bonding, labeling, and environmental crime theories. It examines the proposition that the school environment and experience may generate and maintain delinquent behavior among juveniles.

Differential Opportunities

The criminological work of Albert Cohen, as well as of Richard Cloward and Lloyd Ohlin, identifies delinquency that results from the inability of lower class children to attain desirable success goals. In school, children compete to achieve status conferred by teachers who use a “middle-class measuring rod” in evaluating them. All children, regardless of their upbringings, are expected to subscribe to middle-class ethics, such as hard work, control of aggression, good manners, respect for property, and deferred gratification. Youth who fail to conform to these values will not achieve the goal of educational attainment and subsequent future occupational and financial rewards. Within lower class areas, opportunities are unevenly distributed, which leads to the emergence of gangs and other subcultures that react against middle-class norms by committing acts of random violence, theft, and other deliberate acts of deviant behavior.

While Cohen suggests that delinquent subcultures are hedonistic and commit deviant acts that are nonutilitarian, Cloward and Ohlin maintain that delinquents’ behavior is goal-oriented depending on the opportunities for crime that are available.

Differential opportunity theory suggests that poor school performance may impede goal achievement, leading to delinquency and future involvement in criminal activity. Through the pupils’ failure to receive good grades or be promoted to the next higher grade level, or to receive achievement rewards, the schooling institution is transmitting a message to the youths that they are not achieving a valued goal. This failure to achieve established academic goals could lead to the inability to secure a lucrative career—another valued goal that could lead to involvement in delinquency and criminal behavior. One notable implication of

opportunity theories is that the school itself may contribute to blocking the attainment of goals among some youth, leading to criminal careers.

Strain Theory

Strain theory provides a wealth of explanations appropriate to the study of school-based delinquency. Strain theory, as first proposed by Robert Merton, argues that opportunities are distributed unequally. Within a class-based economy such as the United States, tremendous disparity exists between culturally prescribed goals and the legitimate means available to achieve those goals, which creates pressure or strain. This strain then leads to crime, as the only available means of achieving the goals are through participating in criminal activity. The culturally established goals within the United States, according to Merton, include the elements of (1) goals or aspirations, to which most of society’s members aspire, and (2) the institutionalized means to achieve the goals. In the United States, the goals of society clearly focus on the achievement of economic success. The opportunity to improve one’s economic position are available but are not evenly distributed.

Within the institution of the school, the culturally prescribed goals are reinforced through the focus on achieving academically as a means of acquiring wealth. The schooling institution also overtly reinforces behaviors that are commonly associated with becoming successful, such as perfect attendance, honor rolls, and respect for authority, whereas punishing habits commonly associated with failure within the economic structure, such as tardiness, sloth, and rebellious behavior.

Sociologist Robert Agnew revised strain theory as proposed by Merton into what he called general strain theory. According to Agnew, the failure to achieve culturally prescribed goals of monetary wealth is not the only cause of strain. Frustration and strain can be produced by several “strain-producing” events, as follows:

1. *The failure to achieve culturally prescribed goals.* Within the school environment, sources of strain stemming from the failure to achieve culturally prescribed goals mainly fall on the shoulders of the lower class members of society, many of whom attend impoverished schools. The avenues

available to economic success are limited by resources available, as the focus tends to be on achieving minimum educational standards within dilapidated buildings. The focus then shifts away from academics as a means to success to classroom management and discipline.

2. *The removal of positive stimuli.* This type of strain results from a loss, which could include events that occur during the schooling experience, such as a loss of a parent, divorce, ending of a relationship, and a move to a different school. Youth can react to this source of strain through violent behavior, substance abuse, truancy, or dropping out of school.

3. *The introduction of negative stimuli.* Negative stimuli relates to situations such as abuse, victimization, bullying, teasing, peer pressure, or other problems in school. Delinquent behavior resulting from these negative stimuli can include running away, seeking revenge through violence, or truancy. This version of strain theory predicts that strain can produce negative behavior that leads to delinquency.

Steven Messner and Richard Rosenfeld expanded the original concepts of strain theory by focusing on the implications of the American dream in producing strain, which could then lead to crime. Messner and Rosenfeld discuss strain within the context of institutions, which become subordinate to the overarching dominance of the American dream ethos. Messner and Rosenfeld identify the major social institutions as the economy, polity, family, and education. Institutions promote order within society. In the context of schools, these institutions supposedly provide safety and refuge from the streets and provide socialization to supplement the family and the community in the transmission of certain cultural values. When there is a weakening of these institutions, crime and disorder ensues, which leads to more crime within the community.

Institutional strain theory suggests that in the United States, the economy is the dominant institution, and this dominance can be viewed through three ways: (1) devaluation of the schooling institution, whereby education is viewed as little more than a means to occupational and financial attainment; (2) accommodation of the school to the economy, whereby the school is expected to reflect

the needs of the workplace, and workers often return to school to improve their chances of obtaining promotions; and (3) penetration of the economy into the schooling institution, in which grades are treated as currency to reward acquiescence to the system, and high-stakes testing can directly result in either continued employment for educators or economic sanctions and school closures for institutions that fail to meet minimum standards.

The Social Bond

Travis Hirschi formulated his approach to delinquent behavior in his *Causes of Delinquency* in 1969. His primary interest in this theoretical approach, however, was not what causes youths to become delinquent but rather what traits are most effective at *preventing* delinquent behavior. Hirschi suggests that the school provides opportunities for youths to form prosocial behavioral traits that inhibit delinquency. Strong social bonds with the school are necessary to prepare the youth for learning prosocial skills and avoiding the development of delinquent patterns of behavior in adolescence. Hirschi proposed four types of social bonds that promote socialization and prevent delinquency: attachment, commitment, involvement, and belief.

1. *Attachment:* This element encompasses attachment to the school, teachers, and peers as a control for delinquency. According to Hirschi, poor school performance leads to a rejection of school authorities, which results in delinquent behavior. The youth's attachment to the school depends on his or her ability to achieve academically and on his or her perception of how favorably he or she is viewed by teachers and peers. Attachment to teachers is a stronger control over delinquent behavior than is attachment to peers.

2. *Commitment:* Hirschi's next bond relates to the youth's support of conventional activities. These activities include commitment to scholastic expectations and achievement as a major stake in conforming to prosocial behavior. Youth who choose to delay gratification and invest in schooling as a pathway to achievement will be more likely to experience future rewards and are less likely to resort to delinquency.

3. *Involvement*: This bond closely relates to school-based theories of delinquency, and it comes from the youth's involvement in prosocial school-related tasks, such as extracurricular activities and homework, rather than participating in deviant behavior or idleness. The phrase "idle hands are the devil's workshop" best illustrates Hirschi's third bond in controlling for delinquency. Youth who are busy and "involved" in school-related activities will have little time for delinquent behavior.

4. *Belief*: Hirschi's last bond refers to the youth's ascribing to society's conventional values. What will likely weaken the bond is if the youth views society and its laws as unfair and arbitrarily applied, which leads to an increase in delinquent acts, as the youth rejects the legitimacy of the system.

Labeling

Labeling theory views deviance as a creation of those in power, who define deviant behavior and subsequently label those who break the rules as offenders. As a result of this negative label, the person is likely to be perceived, treated, and reacted to in the future as a "deviant," a "criminal," or a "delinquent." These labels serve to ostracize the individual, who will then associate with others who have been similarly labeled. This leads to an internalization of the label as more people associate the negative label with the deviant, who then begins to act accordingly by engaging in the expected behavior. Therefore, it is not the inherent act that is deviant, but rather the definition applied by those who create and enforce standards of behavior that makes the act deviant. According to Howard Becker, who is one of the major labeling theorists, deviant behavior is behavior that is so determined by people. It is, therefore, not the person's actions that are deviant but rather a consequence of having the label of "offender" applied to the person that makes an individual deviant.

Sociologist Edwin Lemert formulated the assumptions of labeling theory by identifying two kinds of deviant acts: primary and secondary. Primary deviations are the initial acts that attract the attention of those who hold the power to label such acts as deviant, which leads to an informal social reaction.

Deviance Is in the Eye of the Beholder

Labeling provides a rich theoretical basis from which to explore school-based delinquency. Teachers and school administrators may "create" deviant behavior by defining the range of acceptable behavior within their institution. The criteria from which they base their decision can fall outside of the act and be determined by criteria unrelated to the incident. For example, whether the student is a good student, an athlete, or a minority, or even who his or her friends are, can all play a role in determining what acts are labeled as deviant, and what the resulting sanctions will be. The pupil's location in a certain academic "track" can impact whether a certain act comes to the attention of school authorities and results in a reprimand, which could adversely affect the pupil's future status and lead to his or her association with similarly labeled deviant peer groups as well as subsequent involvement in delinquent activities.

Labeling begins early in the schooling of children, and school records, like criminal records, often follow the youth throughout the schooling years and beyond. This paper trail can adversely affect the options available to the youth in later adolescence and adulthood, which can assist in contributing to future deviant behavior.

Situational Theories of Crime

Unlike the previous theoretical perspectives that focus on the behavior of juveniles in explaining school-based delinquency, situational theories analyze the geographic areas that offer opportunities for delinquent behavior and determine how best to prevent crime from occurring in a specific location. The underlying theories of situational crime prevention with implications for schools and crime include environmental criminology, rational choice theory, and routine activities theory.

Environmental Criminology

Environmental criminology explores crime in relation to the daily movement and activities of victims and offenders. It focuses specifically on the geographic location and time the criminal event occurred. Through the use of mapping technology, environmental criminologists look for crime patterns and can relate these patterns to the location

of activities, such as the school, and identify crime hot spots related to the daily flow of victims and offenders through time and space. Property crimes often occur at or near areas where people congregate, such as schools, or along the routes to the school. Schools can generate delinquent activity if shopping malls and convenience stores are located along the juveniles' route to and from school. Juveniles, for example, commit many property offenses on their way to school, between 3 p.m. and 5 p.m. in the afternoon when school is dismissed, and problems can arise in the immediate vicinity of the school at dismissal time, when students are released at one time onto the street. Likewise, the time of day may control for delinquent activity, as a youth who wishes to steal merchandise from a local electronics store is currently in school and cannot commit the theft. Hot spots of delinquent activity within the school building can be identified as areas where teachers and administrators are not normally present, such as restrooms, long corridors, or vacant stairwells.

Rational Choice Perspective

The rational choice perspective is rooted in utilitarian moral philosophy and claims that offenders weigh the costs and benefits before committing a crime. According to this perspective, juveniles are considered rational actors who seek to maximize pleasure and minimize pain. Within the context of the school, juveniles rationally decide where to commit an offense, who or what to target, and how to carry out the offense.

Rational choice theory provides the basis for formulating situational crime-prevention measures that will reduce the opportunities for delinquent acts by (1) increasing the effort to commit the offense by hardening targets, (2) increasing the risks to the juvenile in committing the act, (3) reducing the rewards or benefits the juvenile expects to obtain, (4) removing the excuses that juveniles may use to justify their actions, and (5) reducing or avoiding provocations that may tempt the offenders.

Increasing the Effort

Some of the tactics that can be used within the school include controlling access to the building, having designated points of entry to the building,

installing fencing around the school grounds, and restricting vehicle access to school property.

Increasing the Risks

Tactics that can be used within the school include having security officers patrolling the building, implementing school uniform policies to make juveniles more identifiable on and off school property, issuing student identification badges, and implementing closed-circuit television cameras.

Reducing the Rewards

Tactics to reduce rewards of crime in the school include prohibiting students from carrying portable electronic devices to prevent theft and ensuring that walls remain free of graffiti.

Removing Excuses

Tactics to remove excuses include having well-established rules against bullying, weapons, fighting, and other behavioral problems. Additionally, schools should have a code-of-conduct available for students and parents.

Reducing Provocations

Schools can reduce provocations by staggering recess or class-release times to minimize the number of potential offenders and victims present at one time, shortening the time between class changes, and not allowing students to congregate after school dismissal.

Routine Activities Approach

The routine activities approach analyzes the specific crime target. The target could be a school building or property located in or near the school. Lawrence Cohen and Marcus Felson argue that before a crime can occur, three elements must converge in time and space: a likely offender, a suitable target, and an absence of a capable guardian. Unlike traditional criminological theories, routine activities does not analyze why individuals or groups commit offenses, but rather criminality is assumed. This approach focuses on the prerequisites for a crime to occur and emphasizes that the absence of any one of the three elements will normally prevent a crime from occurring. Cohen and Felson argue that in the United States since World War II, a significant shift

of routine activities has moved away from the home and family, which has undermined guardianship and increased the risk of victimization. Social control through the family, community, and criminal justice system has been undermined by the availability of new opportunities for predatory crime outside of the household, by shifts in labor force participation by females as well as juveniles, and by a reduction in the amount of time that youth spend under adult supervision within the home.

SCHOOL-BASED VIOLENCE PROGRAMS, INTERNATIONAL

During the past 40 years, considerable variation has occurred in the worldwide definition of school

violence. However, within the last 10 years, international scholars have agreed the term *school violence* embraces a broad array of deliberate behaviors intended to cause detriment physically and/or emotionally to students, staff, and property, on or near school grounds. A key component to understanding school violence is that physical, social, and verbal violent behaviors vary in severity and frequency. For instance, physical violence can range in severity from a brief pushing and shoving to severe beating and even the use of weapons. Social and verbal violence may include the spreading of rumors and cyberbullying. Severe types of violence are less frequent and cause more psychological and physical damage, but more frequent and less severe types of violence may have a major negative impact on students' well-being. Research and theory development on these issues is occurring in more than 60 countries.

School violence can have significant harmful effects on children and schools within diverse cultures. Besides bodily injury, the literature suggests that victims may suffer from a range of somatic, psychological, and behavioral outcomes, such as low self-esteem, depression, loneliness, anxiety, suicidal ideation, poor academics, low school attendance, and in uncommon instances, severe episodes of extreme hostility resulting in fatal aggressive acts.

The theoretical and empirical literature indicates that school violence is caused and influenced by a complex interaction of factors on multiple levels. For instance, based on large-scale international samples, Rami Benbenishty and Ron Avi Astor present a global socioecological model that focuses on the interplay between characteristics of individual students and the contexts in which they are embedded—school, family, neighborhood/community, and culture. This work suggests that school violence risk factors may be similar in countries across the world. These theories have direct relevance to practice and intervention as they help identify risk and protective factors associated with the individual student, family, school, peer group, community, and nation. Furthermore, they indicate that schools can play an active role in preventing and responding to violence.

School violence is a global phenomenon, and numerous countries are addressing this challenge. Public interest in the United States, Europe, Middle

East, Australia, and Asia peaked after a series of highly publicized fatal school shootings in the late 1990s (most notably, Columbine High School in Littleton, Colorado). These shootings resulted in important national, state, and local changes in school safety legislation, policy, intervention, large-scale funding, and research. Additionally, the shootings induced several zero-tolerance policies mandating expulsion for possession of weapons, and they provoked a host of interventions such as security guards, metal detectors, video surveillance cameras, and newly built high-security schools. These responses have occurred to some degree or another in countries as diverse as Israel, Iceland, England, Italy, Germany, the United States, Canada, Argentina, Mexico, Taiwan, and Australia. Research suggests that such measures are less effective, discriminate against students of color, and often create the perception that school is “prison like.” However, the tragic Columbine event also triggered a national effort to develop educational and community-oriented evidence-based programs that are free of the negative consequences of draconian measures.

Best Practices and Evidence-Based Intervention Programs

An examination of international successful school-wide intervention programs has several core implementation characteristics. For instance, one characteristic of thriving intervention programs is that they raise the awareness and responsibility of students, teachers, staff, and parents in regard to the types of violence in their schools (e.g., sexual harassment, fighting, and weapon use). Furthermore, clear guidelines and rules are established and used to communicate to the entire school community what procedures should be followed before, during, and after violent events. Successful school-wide intervention programs also focus on getting the school staff, students, and parents involved in the planning, implementation, and sustainability of the program. Additionally, monitoring and supervision is increased in nonclassroom areas (the school yard, hallways, stairwells, bus stops, etc.). In general, the interventions often fit easily into the normal flow and mission of the school setting, and they are culturally sensitive, culturally competent, and immersed within the community/culture of the students.

Numerous examples of model evidence-based programs can be found. Among these are bullying prevention, child development, and school-based intervention programs. For instance, the Olweus’s bullying prevention program, that originated in Scandinavian countries and has been used in countries worldwide, targets 4th- to 7th-grade students and focuses on developing consequences for student behavior, enforcing school rules, conducting classroom workshops on empathy, interventions with bullies, and discussions with parents. The program has been effective at reducing the level of bullying and aggression. The Child Development Project of Victor Battistich and his colleagues targets elementary students. The program focuses on staff training, fostering self-confidence, and engaging students in classroom norm setting and decision making. The results of the project reveal an increased sense of community, more motivation to be helpful, better conflict resolution skills, and stronger feelings of social competence. The Families and Schools Together (FAST) Track program works with at-risk students identified in kindergarten in Australia, England, Austria, Russia, the Netherlands, Canada, and the United States. Components of the program include weekly enrichment, discussion, role playing, emotional understanding, and problem solving, as well as parent involvement. Based on more than 10 years of work, the program has fostered higher scores on emotion recognition and social problem solving and lower scores on aggression. The Promoting Alternative THinking Strategies (PATHS) curriculum, used in a dozen countries, involves 57 lessons taught in grades 1 through 5. These lessons include understanding and communicating emotions, positive social behavior, self-control, and problem solving. Target classrooms experience lower ratings on disruption and aggression as well as higher ratings on classroom atmosphere.

Monitoring and Mapping

In contrast with previous ecological theories on youth violence, gangs, and juvenile delinquency, modern theories of school violence emphasize the practical and theoretical significance of including the “school” in “school violence.” For example, international scholars emphasize how school policies and climate could mediate the effects of negative

external influences (e.g., community poverty and crime) and reduce victimization rates on school grounds. With a deeper understanding of school organizational and social dynamics, researchers from different countries can better comprehend the cultural risk and protective factors associated with the individual student, family, school, peer group, and community as they pertain to external contexts and acts of violence on school grounds. Such knowledge is necessary in the development and cultural transfer of successful international school-wide violence intervention programs.

When evidence-based practices are not tailored to the particular characteristics of the district or local school level, they are frequently unsuccessful. This is true for the use of effective interventions across many countries. This results from the implementation of a program (e.g., a Scandinavian-based bullying program) without accurate local/regional data (a Los Angeles elementary school) on the nature of the school violence problem. Therefore, adoption of evidence-based intervention programs and their subsequent evaluations needs to be based on local school data results gathered from the multiple personal and cultural perspectives of students, teachers, administrators, staff, parents, and community members. One effective way to implement international programs is to gather accurate and useful data by using mapping and monitoring techniques. These types of methods have been used in multiple countries and cultures and are aimed at fitting national and international evidence-based programs to the needs of a particular school.

This data-based method presumes that locally successful programs originate from the subsequent beliefs and assumptions. First and foremost, the effort to “fit” a program to a school requires grassroots participation. Next, the students and teachers in the school need to be empowered to deal with the violence problem. Third, democracy must be at the core of a good evidence-based violence program. Last, schools should demonstrate a proactive vision surrounding the violence problem in their school. This approach embodies conventional beliefs about empowerment and helps to match programs more accurately with specific communities and schools.

This data-driven approach engages and involves the whole school community in a cyclical process of

using a surveillance system of accountability. The school community as a whole assesses safety situations, identifies needs and priorities, and plans policies and interventions based on the most relevant evidenced-based violence prevention knowledge and programs. Implementation, reassessment, and evaluation must be adapted to ensure that interventions coincide with current data results and policy changes in school. Such an approach informs and empowers all members of the school community and leads to globally safer school environments.

SCHOOL-BASED VIOLENCE PROGRAMS, UNITED STATES

School violence includes pushing, hitting, kicking, verbal or physical bullying, and tragic school shootings resulting in serious injuries or deaths. School shootings are relatively rare events, but they draw immense news media attention and raise public concerns about school safety. The shooting incident at Columbine High School in 1999 and the more recent incidents on school campuses have prompted school and justice officials to take actions to prevent school violence. School administrators have implemented a variety of policies and programs, which include installing physical security devices, adding the presence of school police and security officers, training school personnel, and requiring students to carry identification cards or clear backpacks.

A government-funded survey of school administrators found that 8% of public schools in the

United States reported using metal detector checks of students, and that 10% of schools reported having police stationed at their schools at least part time. Physical security devices, such as metal detectors and security cameras, are one step toward preventing school violence, but they have limitations and may provide a false sense of security. Most U.S. schools (94%) have instituted zero-tolerance policies for weapons, alcohol, or drugs, which resulted in more than 5,000 expulsions and more than 8,000 suspensions of 5 or more days. Zero-tolerance policies may partially explain the drop in the number of students who reported carrying a weapon to school (down from 12% in 1993 to 6% in 2001). Nearly all schools have adopted a zero-tolerance policy, but fewer (59%) schools reported that they have included violence-prevention programs in the curriculum.

Most of the focus on school violence prevention has been directed either toward identifying at-risk students through “warning signs” or toward beefing up security through hardware and law enforcement presence. Focusing on the individual student ignores the fact that threats and violence are the results of relationships and interactions among peers. School and community factors that may contribute to school violence have been largely ignored. Abundant research evidence indicates that school climate and environment account for a great deal of school disorder and violent behavior. Violence prevention strategies must therefore take a more comprehensive approach.

School violence is not an isolated problem, but it is closely related to family dynamics, peer relations, community factors, school environment, and organization. A “public health” approach to violence prevention first identifies the causes and risk factors that are related to student violence, and then it directs community resources to develop preventive strategies. According to Delbert Elliott and his colleagues, addressing school violence as a public health problem requires the following series of steps: identify sources of the problem, identify risk and protective factors, perform regular surveillance and tracking of the problem, design community-based interventions, monitor and evaluate each step, and share information about the strategies with parents and the public. The most effective violence prevention approaches are based on sound theory and research. School violence

prevention requires careful assessment, planning, resources, and additional funding.

The best practices focus crime-prevention strategies at the sources of the problem. A comprehensive framework for school violence prevention includes a careful examination of the people, relationships, resources, activities, facilities, and surrounding neighborhoods that make up the school community. The Hamilton Fish Institute outlines at least six areas that should be addressed in comprehensive school violence prevention.

1. *Administrative approaches*: Effective principals with leadership skills; effective academic programs; a disciplinary code that is clearly communicated and consistently enforced, with consequences for inappropriate behaviors; reinforcement for positive behavior; training teachers in classroom discipline; and monitoring and reporting of serious violent behaviors.

2. *School security*: Monitor all areas of school buildings and grounds; ensure sufficient interior and exterior lighting; redesign spaces to remove blind spots; restrict access to inappropriate individuals; remind all students, teachers, and staff of the responsibility for observing and reporting violent behavior; and provide effective use of security personnel, security devices, and police.

3. *School-wide education in violence prevention*: Provide education and skills training to reduce anger, bullying, and violent behavior; offer opportunities for students to practice social skills and resist negative pressures from peers; integrate age-appropriate learning materials into the curriculum; and use banners, posters, and special events to supplement violence prevention curricula.

4. *Counseling*: Be aware of the emotional needs, fears, and stressors of students; expand counseling services for perpetrators, victims, and witnesses of violence; refer students for diagnostic services and counseling interventions; and provide teachers and staff with information to aid in identifying and responding to disruptive and violent behaviors.

5. *Alternative education*: Provide alternative programs for students expelled or suspended for weapons carrying or violent acts; use specially trained school staff; offer individualized instruction, low student-to-teacher ratios, and innovative

presentations; and include training in anger management, nonviolent communication, conflict resolution, and the use of mediation.

6. *Community involvement*: Offer parents training in communication, establishing rules and discipline, proper safeguarding of weapons in the home, family management, and skills to reduce the stress and challenges of raising children; develop clear communication and working relationships with police, juvenile probation, mental health, and other social service agencies; encourage businesses to offer financial support for programs and services, training for job skills and internships for students, training for employees in parenting and family management, and flexible scheduling for employees with school children; and develop partnerships with local government, community organizations, and faith-based organizations to help prevent youth violence.

School violence has roots in the family, popular culture, peer relationships, and the school environment. Effective violence prevention demands our commitment and our best resources. Failure to do so will continue to have a detrimental effect on school safety and the quality of education for all children and youth.

SCHOOL CRIMES, ELEMENTARY THROUGH HIGH SCHOOL

School crimes are those committed on school property during regular hours of operation against students, faculty, staff, or school facilities. It is often the case that those students who are committing crimes at school are also the victims of crimes themselves. Schools are places where a variety of crimes and opportunities for crimes occur every day. If a particular type of crime exists in the community a school is nested within, it is likely that type of crime will find its way into the area's schools. This is especially troublesome considering that crimes which occur at school disrupt learning, negatively impact society's most impressionable and susceptible members, and may have long-lasting implications compared with crimes committed at other places.

Schools are busy places that bring individuals together from all around. From elementary schools through high schools, a diverse group of children, adolescents, and young adults are brought into the same space to interact with each other—some are potential offenders, others are potential victims, and many experience both roles. As children enter school around age 5, their early problem behaviors are often manifested as aggression, age-inappropriate behavior, and acting out. As children grow into adolescence and young adulthood, their school transgressions become actual criminal behavior such as vandalism, drug use, gang involvement, and violence against other students or teachers.

Clear evidence in the literature indicates that both offending and victimization peak during adolescence and young adulthood. This means that individuals are most likely to participate in a crime between approximately the ages of 12 to 25. These years are also the time when youths are most likely to be victims of a crime. This is because of a variety of factors, such as greater exposure to offenders, demographics, peer influences, and many others. Research has also shown that adolescents with delinquent friends are more likely to be delinquent themselves and are more likely to be victimized. In other words, peer influences matter with respect to likelihood of both victimization and participation in crime. One's routine activities,

such as spending time with family, studying, participating in team sports, or even playing video games and spending time online are examples of activities that comprise youth lifestyles. Various lifestyles, including deviant lifestyles, ultimately affect one's likelihood of victimization.

Many issues must be considered when studying the subject of school crimes, and although they cannot all be discussed here, it is important to understand the scope of the problem. Among these are the prevalence of victimization, threats against peers and teachers, use or presence of weapons, discipline problems, gang presence, drug availability, hate speech, and bullying. It is clear that many types of crimes occur in U.S. schools. Based on a variety of national data sources, such as the Uniform Crime Reporting (UCR) Program, the National Crime Victimization Survey (NCVS), and reports by the U.S. Department of Education, it is possible to get an idea of how serious the situation is and what types of crimes are being committed. Trends indicate that the most frequent crimes to occur in schools are property crimes, such as theft of a backpack, whereas the most serious and well known are violent offenses, such as school shootings.

According to a recent report by the U.S. Department of Justice and the U.S. Department of Education, males, students in the "other" race category, youths ages 12 to 14, those living in urban areas, and those living in households that earn \$50,000 to \$74,999 per year are the most at-risk groups for school victimization. Table 1 shows student victimization data for select student and school characteristics for 2005. In 2005, 28% of students age 12 to 18 reported that they had been bullied at school within the past 6 months, and 14% of 9th to 12th graders said they had been in a fight on school property. A 1997 study of middle and high schools conducted by the National Institute of Justice found that the most frequent location for violent acts to erupt at school was in the classroom, followed by the hall or stairs, and then the school bus. The Federal Bureau of Investigation (FBI) reports that 12% of all hate crimes committed in 2006 occurred at public and private schools or on college campuses. Students are not the only victims of school crimes. For example, in the 2003 to 2004 school year 3.4% of teachers reported having been physically attacked by a student within the last 12 months.

Source: From Dinkes, R., Cataldi, E. F., Lin-Kelly, W., & Snyder, T. D. (2007). *Indicators of school crime and safety: 2007*. Washington, DC: U.S. Department of Justice, Bureau of Justice Statistics. Copyright 2007 by the U.S. Department of Justice.

†Data not available.

1. Violent crimes are classified as simple assault, aggravated assault, robbery, sexual assault, and rape.
2. Serious violent crimes are classified as all violent crimes excluding simple assault.
3. Other races include Native Americans, Native Alaskans, Asians, Pacific Islanders, and those identifying with more than one race group.

Examining the situation at only one point in time can be disconcerting. However, while pondering these statistics, it is important to keep in mind that between 1992 and 2005, school crimes declined in a pattern consistent with the decline in the national crime rate. During that same time, students age 12 to 18 were also more likely to experience a violent victimization away from school than they were at school. It may be possible to attribute some of the recent decline in school crimes to crime-prevention efforts undertaken by schools, school districts, and communities. Some of these include initiating closed-campus policies, initiating zero-tolerance policies, hiring police officers to work at schools, increasing surveillance and hall patrols, mandating students to wear school uniforms, and even installing metal detectors at school entrances. It is encouraging that although school crime remains a serious problem with far-reaching consequences, incidents have been fewer

in recent years, and schools have undertaken efforts to keep schools safe.

SCHOOL SHOOTINGS

School has historically been considered a safe place for youths. When killings occur in schools or on school grounds, it draws special attention for many reasons, including the following: (1) killings in school are relatively rare, (2) in many cases killings in general are rare in communities where school shootings have occurred, (3) in many cases the offenders—often students themselves—have gained unusual (i.e., illegal) access to the firearms used in their assaults, and (4) the victims are by any standard undeserving of their fates, and in many recent, well-known cases, innocent children have been victims of a rampage. After learning about school shootings, it is therefore typical for both social scientists and the general public to desire to know what happened, why, and how to prevent such killings from happening again. This entry defines and describes the incidence of school shootings, efforts to explain school shootings, and policies that have resulted from these tragedies.

Definition and Incidence

Public perceptions of school shootings—particularly in the United States—are heavily influenced by the

shootings at Columbine High School in Littleton, Colorado, in 1999, in which two students killed 12 students and 1 teacher, and wounded 23 others. According to sociologist Glenn Muschert, the Columbine event is an example of a *rampage shooting*, where the shooters, who are usually students, attack students and/or teachers with the purpose of seeking revenge on those who have wronged them or gaining power in some fashion. Muschert argues, however, that the rampage shooting is only one of five types of school shootings, albeit the type that gets the most media attention. Others include *terrorist attacks* (e.g., the assault on the school in Beslan, Russia in 2004); *targeted shootings*, where the shooting is perpetrated on particular individuals in the school; *mass murders*, typically committed by someone who is not a student at the school (e.g., the 1996 shootings in Dunblane school in Scotland); and *government shootings*, where school members are shot in response to collective behavior such as protests or rioting (e.g., the 1970 killing of four Kent State students by National Guard troops).

Despite the media attention to school shootings—and rampage shootings in particular—studies of crime and victimization in schools tend to conclude that incidents of serious violence in schools are relatively rare, and school shootings are rarer still. Victimization data in the United States indicate that of all homicides involving school-aged children, only 1% to 2% occurs at school. The number of firearm-related homicides in, en route to or from, or at an event sponsored by public or private primary and secondary schools has been 20 to 30 per year on average from 1999 to 2008. The number of shootings occurring on college campuses is much smaller. Nevertheless, public polling finds school shootings and school violence to continue to be a concern among survey respondents.

Comprehending School Shootings

Although lethal and nonlethal forms of violence have been studied by social and behavioral scientists for some time, a specific focus on school violence and school shootings has developed as a subset of violence studies in the late 1990s. It is no coincidence that much of this research effort came about in response to the shootings in Littleton

Table I Selected recent school shootings

<i>Year</i>	<i>Location</i>	<i>Shooter(s)</i>	<i>Victims</i>	<i>Type of Shooting</i>
1999	Columbine High School Littleton, CO	Two male students	15 killed 23 wounded	Rampage
2001	Santana High School Santee, CA	Male student	2 killed 13 wounded	Rampage
2002	Gutenberg School Erfurt, Germany	Male student (former)	18 killed 6 wounded	Rampage
2002	Red Lion Junior High School Red Lion, PA	Male student	2 killed	Targeted
2006	W. Nickel Mines Amish School Nickel Mines, PA	Male non-student	5 killed 5 wounded	Mass murder
2007	Virginia Tech Blacksburg, VA	Male student	33 killed 15 wounded	Rampage
2008	N. Illinois University DeKalb, IL	Male student (former)	6 killed 17 wounded	Rampage
2008	School of Hospitality Kauhajoki, Finland	Male student	11 killed 2 wounded	Rampage
2008	Dillard High School Fort Lauderdale, FL	Female student	1 killed	Targeted

(as well as previous incidents in Jonesboro, Arkansas, and Pearl, Mississippi). Efforts to understand school shootings have ranged from the microcosmic—such as a focus on the psychological predispositions of individuals to become violent in the school setting—to the macrocosmic, in which school, family and community contexts (either singly or as a whole) are examined and viewed as significant contributors to understanding why school shootings occurred. Other potential contributors to school shootings that have been studied include violent video games and films, guns, drugs, and an overall decline in morality.

A recent example of such research is sociologist Ralph Larkin's case study of the Columbine shootings. Larkin analyzed reports and interviewed former Columbine students, teachers, administrators, and members of the Littleton community in an attempt to piece together an understanding of why Eric Harris and Dylan Klebold shot and killed 12 fellow students and a teacher (and eventually

themselves) on April 20, 1999. Larkin focuses on the youth culture in the school, highlighting the intimidation and bullying of students in one clique by another. Other, macrocosmic forces discussed by Larkin include how the religious intolerance of Littleton may have played a role in events leading up to the shooting, the rise of a paramilitary culture in the United States in the 1990s, and the importance of media and "celebrity" to Klebold and Harris.

Policies Resulting From School Shootings

As a result of incidents similar to and close in time to the Columbine shootings, many schools reformed both security and disciplinary policies in an attempt to respond to the perceived (if not actual) threat of a shooting on their campuses. Examples of changes in school security include both new and existing technologies; most notable in relation to school shootings have been an increased use of metal

detectors and law enforcement personnel (most likely as “school resource officers”) working full-time on school grounds. Changes in disciplinary procedures have included increased use of so-called zero-tolerance policies, which enhance punishment for what may have been previously viewed as minor infractions. Although victimization data indicate that school crime on the whole has declined, the overall decline began before many of these policies were put into effect. In the United States, school suspension rates have increased since 1999, and minority students are disproportionately represented among suspended students. Sociologist Aaron Kupchik has argued that these security changes are indicators of U.S. schools’ more punitive approach to social control. Less common than changes in security practices, although potentially more effective in terms of safety, are the implementation of violence prevention programs. The National School Safety Center is a resource for schools looking for model prevention programs.

SCHOOL TEACHERS/STAFF, VICTIMIZATION OF

Although a voluminous amount of research examines student victimization in school settings, only a few studies have looked at teacher and staff victimization in schools. Despite the perception that teachers and staff members are victimized regularly by violent crime in the school setting, empirical evidence shows that this is simply not the case. This entry examines the problem of teacher and staff victimization by both students and parents.

According to the Bureau of Justice Statistics, teachers have relatively little risk of violent victimization in the workplace when compared with those in mental health, law enforcement, transportation, and retail industries. Although special education teachers have the highest risk of violent victimization, their risk is still much lower than those employed in law enforcement professions and is about equivalent to those of mental health professionals and those working in retail sales. Middle- and high-school teachers have slightly less risk of victimization than special education teachers, and elementary teachers have one of the lowest rates of victimization of any of the aforementioned professions. University teachers have the lowest risk of violent victimization of any of those groups studied. Additionally, evidence from both Canada and the United States suggests that teachers are much less likely than taxi drivers, law enforcement officers, retail workers, and health or social service workers to be victims of homicide during the course of their employment.

Victimization by Students

Despite the relative safety from violent crime when compared with other professions that comes from working in an educational setting, anecdotal evidence is regularly used to suggest that teachers are at greater risk of victimization in the early part of the 21st century than at any time in the history of public education. Again, the empirical evidence does not support this argument. Probably the most comprehensive examination of teacher and staff victimization is a collaborative annual effort between the National Center for Education

Statistics and the Bureau of Justice Statistics titled *Indicators of School Crime and Safety*. The most recent report indicated that, although the percentage of teachers that reported being physically attacked has remained relatively constant (3% in 1993–1994 and 4% in 2003–2004), a smaller percentage (7%) of teachers reported being threatened with injury in 2003–2004 than in either 1993–1994 (12%) or 1999–2000 (9%). As such, the risk of violent victimization in educational settings, while still low, has decreased over time.

Other research that focuses on nonviolent victimization among teachers, however, does find that teachers regularly have items stolen from their desk and are often victims of verbal abuse and, to a lesser extent, sexual harassment. Recent evidence suggests that a substantial minority of teachers are victims of verbal abuse and threats, whereas a small minority are victims of workplace bullying and sexual harassment. One in 10 principals also reported that verbal abuse of teachers by students occurred on either a daily or weekly basis; this problem was more significant at schools with 1,000 or more students and in schools where most students received free or reduced lunch.

Additionally, student behavior that interferes with the teacher's ability to deliver effective instruction and disrupts the classroom environment is often found in schools. However, some research suggests that these troublesome behaviors are far more threatening to teachers and staff in educational environments than their counterparts in mental health environments. As such, these disruptive behaviors among students often create an educational environment where teachers feel their authority is threatened and create problems in the teachers work environment.

Victimization of Teachers and Staff by Parents

As the research reviewed above suggests, a limited amount of research estimates the prevalence of teacher victimization by students. Nevertheless, an even larger void remains in the research regarding teacher and staff victimization by parents. This lack of attention is somewhat perplexing, given the large body of research that has identified parental attitudes as a significant source of stress for teachers and staff. In fact, the strain of dealing with

parents has been cited as one of the primary factors in the resignation of new teachers.

Parental involvement in youth sports and debates between parents and teachers regarding academic grades has resulted in the emergence of a typology of "pushy parents" who have been linked to a range of problematic behaviors, which include serious acts of physical aggression and even murder. Although society at large has recognized that pushy parents exist and educators have spent a significant amount of time developing strategies to address the inherent conflict in parent-teacher relationships, limited academic research examines parental aggression toward teachers.

Although the number of documented incidents that involve parental aggression toward teachers and staff in the school setting is even smaller than the number of documented incidents that involve student victimization of teachers, these situations do exist. During 2001, 140 members of the National Association of Head Teachers reported being assaulted in the United Kingdom. In the United States, Philadelphia experienced 57 such assaults in a 6-month period. Other research has determined that more than half of all teachers had been threatened by a parent at some point in their career. These threats involved three primary types: verbal threats accompanied by intimidation, non-contact threats accompanied by intimidation, and intimidation with physical contact.

The limited research that has attempted to document parental aggression toward teachers does provide some important information about parental victimization of teachers and staff in the school environment. First, mirroring previous research with students, the most prevalent form of parental victimization of teachers was verbal victimization, as more than one third of teachers indicate that a parent of a child at the school had screamed at them at least once in their career. More than one in four teachers indicate that a parent of a child at the school has used profanity directed toward them, and more than one in five respondents indicated that a parent of a child at the school had called them on the phone and harassed them at some point in their career. More than 1 in 10 teachers indicated that a parent had verbally threatened them in their career or had threatened to do professional harm to them by using their personal connections. Second, very few

teachers had been victims of parental violence in the school setting. About 5% indicated that a parent had detained or attempted to detain them in a location in which they did not want to be, and less than 2% had a parent push, hit, or attempt to push or hit them in their career.

Despite the small number of teachers that had been victimized by parents, several teachers indicated that they had considered changing professions because of problems they had with parents and had avoided school events because they wanted to avoid parents with whom they had confrontations; in fact, a small percentage (about 2%) indicated that they had even considered carrying a weapon to school to protect themselves.

This research also provided some important insight into the causes of problems with parents. Discipline was the most important cause of problems between respondents and parents, although several respondents also indicated that conflict over grades was another important cause of conflict with parents. Small percentages of respondents also indicated that special education issues and attendance issues created conflict with parents as well.

Despite the relative safety of the school setting, many teachers remain fearful of victimization in the school setting. In fact, the greatest fears of both teachers and education majors in the university setting were guns, hostage situations, and violent victimization; the infamous school shooting at Columbine in 1999 was referenced by both groups as having the most impact on their fears in the school setting. In an effort to alleviate these fears, schools have taken several steps to reduce the likelihood of teacher and staff victimization even more. Some of these steps include limited access to buildings and grounds both during and after school hours, requiring faculty and staff to wear badges or picture identification, and using security cameras.

Educating Teachers and Staff About Victimization

The current state of research regarding teacher and staff victimization at school indicates that teachers and staff have relatively little risk of violent victimization in their daily employment in the school setting. Despite the protected nature of their

employment, however, both university students considering employment in schools and active teachers still remain fearful of violence in these settings. Interestingly, these groups are far less fearful of verbal assaults (from both students and parents) and property crime, events that happen far more often in the school setting. As such, additional efforts should attempt to educate both teachers and staff regarding the facts about teacher and staff victimization and their relative safety from harm in the school setting. A more rational consideration of their risk of violent victimization may decrease fears of this victimization and make more individuals consider employment as teachers and, once employed, remain in the educational setting.

SCHOOL VIOLENCE

Violence in the nation's schools has gained a great deal of attention since the high-profile school shootings during the 1990s. The Columbine High School massacre in 1999 was the pivotal event that launched the problem of school violence into the media spotlight. Twelve students and a teacher were killed that day, and 23 others were wounded before the assailants took their own lives. This tragic event created an implicit and growing fear that these events would continue to occur and even escalate in scale and severity. Consequently,

students, parents, teachers, school officials, law enforcement, and community members frantically searched for answers as to how this could have happened and what, if anything, could be done to prevent it from re-occurring in the future. This entry explores the definition, prevalence, and risk factors associated with school violence. It concludes with a discussion of the school response to the problem of school violence.

Definition

The definition of what constitutes school violence continues to evolve. Until recently, the definition of school violence was considered in terms of only physically aggressive acts such as homicide and weapon-related threats. This narrow, yet widely used definition stems from the considerable attention that the media has paid to school shooting incidents that result in deaths and serious injuries. Although this type of violent activity in schools is newsworthy, recent research suggests their occurrences are relatively rare. Thus, whereas serious incidents of school violence resulting in death or serious injury understandably draw the most media and public attention, fights, bullying, harassment, and verbal threats (often referred to as “everyday school violence”) occur far more frequently. The omission of these broader dimensions of school violence caused researchers and school administrators to miss much of the content and many causes of more visible forms of physical violence manifested by students within schools.

However, as educational associations across the country began to take a position on the problem of violence in our schools, the definition of what constitutes school violence has evolved to include a broader range of activities, such as verbal assaults, bullying, pushing and shoving, harassment, intimidation, and teasing. The expansive definition of school violence allows for the inclusion of both overt (e.g., shootings, aggravated and simple assaults) and subtle forms of violence (e.g., teasing, harassment, and intimidation) that allow schools to focus on making schools safe as well as violence free. By broadening the traditional definition of school violence, prevention initiatives must also be expanded. Thus, trying to prevent school violence only in terms of physical security measures that are designed to keep guns and other weapons out of

schools is no longer enough. Although such types of measures have their place, in the prevention of school violence, a whole range of more comprehensive measures must be employed that reflect the diverse types of behaviors that may violate a school’s educational mission or climate of respect.

Prevalence

Although some studies and the media coverage may suggest that serious forms of school violence are on the rise, an overwhelming amount of evidence suggests that school violence, particularly school-related homicides, is a relatively rare event. In fact, it is estimated that the probability of becoming a victim of a school-related shooting is roughly one in 1 million, which thereby suggests that the nation’s schools are safe from extreme acts of violence. When considering lesser, yet still severe forms of violence, the research shows that physical attacks without a weapon, theft or larceny, and vandalism are much more common than school shootings. In addition, careful attention must also be paid to the expansive forms of behavior that fall under the broader definition of school violence.

Concerns about violent and aggressive behavior in schools should not be ignored; however, individuals are often fearful of and intimidated by other, less serious types of violence. These lesser forms of school violence include physical aggression such as shoving and pushing, face-to-face verbal harassment, intimidation, public humiliation, and teasing. Although there may be no visible wounds, one cannot discount the powerfully negative emotional and psychological costs associated with these forms of behavior. Victims of violence often report feelings of vengefulness, anger, self-pity, and fear. Left untreated, such reactions can evolve into depression, absenteeism, poor academic performance, physical illness, and suicide.

Student Victimization

During the 2005–2006 academic year, the number of students enrolled in pre-kindergarten through 12th grade is estimated to be around 55 million. The number of school-associated deaths during the 2005–2006 academic year was 17, which includes 14 homicides and 3 suicides. More prevalent forms of violence included simple assaults, thefts, vandalism,

and bullying. In fact, at least 25% of students reported that they had been bullied at school during the previous 6 months. The consequences of this victimization cannot be underestimated.

Students who are afraid of school violence often exhibited less positive feelings toward school, had lower academic achievement, experienced less effective social interaction, and had lowered self-esteem. Students who were victims of violence at school are also more likely to internalize problems, have fewer friends, experience low friendship quality, and become fearful. Students are increasingly more likely to report being afraid of an attack at school than away from school. Consequently, students who feared school violence often experienced apprehensiveness among their peers, brought weapons to school for protection, exhibited reduced concentration on assigned tasks, avoided school, and lacked school enjoyment. Undoubtedly, violence makes students fearful and affects their readiness and ability to learn, which detracts from a positive school environment.

Teacher Victimization

The threat of school violence changes not only the school climate for students but also the work environment for teachers. Teachers can also experience many diverse forms of school violence, which range anywhere from rare but serious offenses, such as assault or death, to frequent and pervasive experiences of theft and verbal threats. Factors commonly associated with teacher victimization include the location of the school (e.g., urban, suburban, rural), the school level (e.g., elementary or secondary schools), and whether the school was public or private. Teachers from urban schools were more likely to be victimized than teachers from suburban and rural schools. In addition, secondary school teachers were more likely to be victimized than elementary school teachers. Furthermore, teachers from public schools were more prone to victimization than those teachers from private institutions. The resultant consequences of teacher victimization at school cannot be ignored.

Although most information regarding school violence has focused almost exclusively on students, violent and nonviolent acts against teachers that result in their fear at school should not be

ignored. Teachers who feel unsafe in their classrooms tend to become unmotivated and less committed to their educational mission. In addition, poor teacher performance may affect students' performance as well as their behavior adversely. For example, teachers in disorderly schools may spend a large proportion of their time coping with behavior problems than academic instruction. Furthermore, teacher turnover remains higher in schools plagued with violence and disorder.

Risk Factors Associated With School Violence

The empirical literature suggests the risk factors associated with school violence cannot be attributed to one single cause; rather, it stems from a combination of individual, relational, situational, and environmental factors that interact to increase the likelihood of school violence. Additionally, even with the complexity of human behavior and some central factors associated with school violence (e.g., retribution, self-defense, saving face, and promoting one's image), unique factors are associated with each specific form of school violence. Finally, risk factors may also differ depending on the gender of the perpetrator, the type of the school (e.g., elementary, middle, and high school), characteristics of the school (i.e., public or private), and location of the school (e.g., rural, suburban, urban). Hence, although it may be tempting to use risk factors to estimate the potential for violence within any given school, administrators should proceed with caution. The application of such proactive or risk-assessment measures may result in false positive and negative identifications.

Theoretical Explanations

The number and complexity of theories designed to improve our understanding of school violence is notable and speaks to the complexity of the problem facing our nation's schools. Understanding the causes of school violence through the use of criminological theory is essential to make rational, informed responses to the problem. Theoretical explanations of school violence can be categorized into two broad categories: macrolevel and microlevel explanations. Macrolevel explanations of school violence focus on the social and cultural environment in

which adolescents grow up and examine whether certain factors (e.g., crime rates, cultural deviance, status frustration, and social disorganization) have a link to school violence. In contrast, microlevel theoretical explanations focus on the behavior of individuals. For instance, a microlevel theory attempts to explain why some youths engage in violent behavior at school whereas others do not. Microlevel theories designed to examine school violence may examine such factors as an individual's ability to make rational decisions and exhibit self-control. In addition, microlevel factors may also include interactions with pivotal social forces in an adolescent's life to include his parents (i.e., social learning theory and self-control theory) and friends (i.e., differential association theory).

Of course, no single explanation can account for all acts of violence at school, however, most of the explanations of school violence at the macrolevels and microlevels do offer accurate descriptions for why youths engage in delinquency under different circumstances. Thus, just as there are a variety of causes, therefore, policymakers must also take a variety of approaches to deal with the problem.

Response and Prevention

In the wake of the Columbine tragedy, many schools have turned to specific strategies that can protect schools from violence. Many schools around the country have developed tough zero-tolerance policies, not to mention the use of metal detectors. Unfortunately, little evidence is available to suggest that any single strategy can keep schools safe. To complicate matters even more, serious and dramatic incidents of violence seem frighteningly random, raising concerns about whether such violence is indeed preventable. Despite these concerns, efforts have been made to take a comprehensive approach to reduce the range of incidents that constitute school violence.

Nationally recognized researchers in the field of school violence have begun to look at what works and what does not in the prevention of school violence. Consistently, programs that cut violence effectively are mainly proactive rather than reactive in nature. Such proactive programs typically involve families, students, and the community. Some of the most common multidimensional programs involve peers, families, and communities.

Peer Mediation Programs

In response to preventing school violence, many schools across the United States have begun to consider making violence prevention and conflict resolution part of their curricula. Such programs rely on ongoing instruction and discussion to change the perceptions, attitudes, and skills of students. These types of programs are successful because they address the complexity of the problem and take on a broader problem-solving approach. Peer mediation programs use a group of student mediators who are taught an interest-based negotiation procedure, along with communication and problem-solving strategies. The goal of this training is to assist peers in settling disagreements without confrontation or violence. In most of these programs, students come voluntarily and are guided by peer mediators to move away from blaming each other to devising solutions acceptable to all parties.

The early conclusions about peer mediation programs tend to show them as a promising strategy for improving the school climate over time. The use of peer mediation programs are believed to change substantially the way students approach and settle conflicts. For example, students involved in peer mediation often express a greater willingness to help their friends avoid fights while helping them to solve their conflict. In addition, students who participate in peer mediation programs are less likely to buy into the mind-set that some students deserve to be victimized. With the implementation of a peer mediation program, adequate attention must be paid to the details of planning and training those involved. A follow-up analysis must be enacted to ensure that the program is meeting the intended goals. In sum, peer mediation has been touted as a broader school-wide program approach to reducing the problem of school violence. In its initial analysis, peer mediation seems to be a promising tool that can help teach students methods to settle their conflicts without resorting to violence.

Parent Involvement

Parent involvement provides an important opportunity for schools to enrich current school programs by encouraging and bringing parents into the educational process. Increased parent

involvement is correlated with increased student success, increased parent and teacher satisfaction, and improved school climate. Schools can encourage involvement in many areas, which include parenting, learning at home, communication, volunteering, decision making, and community collaboration. Parent programs that have shown the most success are built on positive interactions and take careful consideration of the unique needs of the community. Although the specifics may vary from school to school, parent involvement programs share the goal of increasing parent-school collaboration to promote healthy child development and safe school communities.

Conclusion

School violence and the problems that stem from it continue to plague schools across the United States. Although the problem of school violence remains at the forefront of societal consciousness, educating the public and providing awareness to school officials, teachers, students, parents, and community members is critical. Educational initiatives have promoted the fact that school violence is a multifaceted problem spanning in seriousness from teasing to school shootings. Even though school shootings are widely covered in the media, they are far less common than minor forms of violence at school. In addition, even though some commonalities may exist among incidents of school violence, there is little evidence to support any single, accurate shooter profile or any common set of risk factors for violence. Consequently, any profile that has been created carries with it a considerable risk of false positives. In other words, some students may fit the profile but may never engage in such violence. Educationally driven programs have also focused on the victimization of school students and teachers because the consequences of their experiences can be devastating. Understanding that there is no one-size-fits-all solution to the problem of school violence is probably the biggest theme that can be taken from the extant literature. Although on the surface incidents of violence at school may seem similar, the dimensions of human behavior and reasoning suggest the opposite. Hence, it is not likely that one solution will clearly work in all cases, so no single solution should be mandated. Thus, schools can be free to experiment

with different comprehensive policies and methods of response to find the solution that works best for their own needs. Finally, the response to and prevention of school violence continues to evolve as more research is conducted and used to inform our current and future policies.

SEATTLE SOCIAL DEVELOPMENT PROJECT

The Seattle Social Development Project (SSDP) was a school-based intervention for students in grades 1 to 6 that used a risk-reduction and skill-development strategy to improve a range of academic, behavioral, and emotional outcomes for participating children and youths. This entry provides a basic overview of the project, program participants, and published evaluation research.

The theoretical basis for the SSDP is the social development model. This model contends that family bonding and school bonding in children can be enhanced by providing children with opportunities for greater involvement in their schools and families, helping children develop the necessary skills for fuller participation with their schools and families, and consistently reinforcing this skillful participation. The social development model also proposes that strong bonds to families and schools help set children on positive developmental trajectories, which in turn lead to more positive outcomes later in life. The SSDP was funded by the National Institute on Drug Abuse (Prevention Research Branch), the Office of Juvenile Justice and Delinquency Prevention, the Robert Wood Johnson Foundation, and the Burlington Northern Foundation.

The SSDP began in 1981 with a combination of student, teacher, and parent components. Program participants initially included students in grades 1 to 6 in eight public schools located in Seattle, Washington. These students were from mixed

socioeconomic and racial/ethnic backgrounds. Four years later, the study was expanded to include 5th- and 6th-grade students in 10 additional Seattle public schools. The program was implemented during the school day by regular classroom teachers.

Program Design and Curriculum

Teacher training involved 5 days spread throughout the school year, and teachers were regularly observed by SSDP staff and the school principal. SSDP classroom teachers were trained in instructional methods that involved the following three major components: proactive classroom management, interactive teaching, and cooperative learning.

1. *Proactive classroom management:* Teachers were trained to establish positive classroom management practices and expectations before problem behaviors begin to develop. Classroom routines were meant to be implemented at the beginning of the school year to create a consistent pattern of expectations for students and to avoid issues such as conduct problems and academic failure.
2. *Interactive teaching:* Through interactive teaching, teachers ensured that students master specified learning objectives before moving on to new material, graded based on student improvement over past performance, and monitored students frequently to assess their progress.
3. *Cooperative learning:* This method involved designating small groups of students with a range of abilities and backgrounds to work together on learning curriculum material.

In addition, SSDP students in the 1st and 6th grades received specific instruction in cognitive and social skills. This instruction was also provided by the regular classroom teachers, who received additional training in the specific curricula provided to students in those grades.

- During grade 1, students participated in the “Interpersonal Problem-Solving” curriculum, which teaches communication skills, decision making, negotiation, and conflict resolution.

- Sixth-grade students received a 4-hour refusal-skills training program. This program aimed to assist students in recognizing and resisting the types of social influences that may encourage problem behaviors, such as drug use or risky sexual behavior, and developing options for positive and productive alternative behaviors.

Parents of children who participated in the SSDP were offered a series of education workshops taught by SSDP staff, which focused on child behavior management skills, academic support skills, and skills to reduce children's risk of drug use. Three different parent classes were offered, which corresponded to the grade level of the child.

- Parents of students in grades 1 and 2 were offered the seven-session "Catch 'Em Being Good" curriculum. The program teaches parents effective methods for conveying expectations about behavior, identifying and reinforcing desirable behavior, and determining appropriate responses for negative behavior.
- Parents of 3rd-grade students were offered the four-session "How to Help Your Child Succeed in School" curriculum, which was designed to improve communication between the parent and child and increase the parents' level of involvement in their child's academic activities.
- Parents of 5th- and 6th-grade students were offered the five-session "Preparing for the Drug (Free) Years" program. This skills-training curriculum aims to help parents in establishing family policies, enhancing family communication, and teaching children resistance skills.

Evaluation Methods

The SSDP was implemented and evaluated in Seattle, Washington. The program began with a group of students entering the 1st grade in eight Seattle public schools in fall 1981. At that time, one entire school was assigned to the treatment condition (SSDP), and one entire school was assigned to the control condition (no program). In the remaining six schools, students and their teachers were randomly assigned to treatment or control classrooms. During the next three school years, newly entering students in grades 1 to 4 were randomly assigned to treatment or control

classrooms and were added to the study sample. Originally, 520 students remained in the sample at the end of 2nd grade.

In fall 1985, when the original subjects entered the 5th grade, the SSDP was expanded to include all 5th grade students in 10 additional Seattle elementary schools. These 10 schools were matched to the original eight schools with respect to the grades served and the percentage of students who lived in high-crime neighborhoods. Schools were then nonrandomly assigned to either the treatment group or the control group, and students participated in the SSDP for 2 years (grades 5 and 6). Therefore, the 10-school expansion resulted in the following three groups for analysis purposes:

1. Students participating in the SSDP from grades 1 to 6 (full intervention)
2. Students participating in the SSDP in grades 5 to 6 only (late intervention)
3. Students in the control group, which combined the control group participants from 1981 with those that were added to the study in 1985

When students were in 5th grade, study participants and their parents were asked for consent to participate in the longitudinal study of the SSDP. A total of 643 5th-grade students agreed to participate, of which 156 were in the full-intervention group, 267 were in the late-intervention group, and 220 were in the control group. (Several students were also assigned to a parent-training-only group; however, the results for this subgroup have not been assessed and are not reported here.)

Overview of Key Evaluation Findings

The first evaluation of SSDP was published in 1991 and assessed students in the original eight participating schools in the spring of 2nd grade. Numerous longitudinal follow-up studies of program effects have been conducted on the full-intervention and late-intervention program participants and the comparison group. The impact of the SSDP was evaluated at multiple time periods, which included evaluations while the intervention was ongoing (at ages 7, 8, and 10), shortly after the end of the intervention (age 13), and at

6- and 9-year follow-ups (ages 18 and 21). Most SSDP evaluations are based on the quasiexperimental portion of the study (i.e., including the 10 schools that began in 1985 and that were not randomly assigned to experimental group). Examinations of school characteristics for evidence of bias because of the nonrandom group assignment generally find that schools in the treatment and control groups were similar with respect to observable characteristics, such as gender, ethnicity, childhood poverty, residential stability, and so on.

Each evaluation period of the SSDP produced significant, positive treatment effects, although the findings were not always consistent among time periods or across all outcomes measures. These findings sometimes differed by gender or race. Some evidence indicates that the full intervention (grades 1–6) may be more effective than the late intervention (grades 5–6 only). Examples of significant program impacts found during at least one evaluation period include decreased aggressiveness, increased social competence, lower rates of alcohol and cigarette use, lower rates of delinquency, lower rates of drug selling, lower numbers of lifetime court charges, increased levels of school bonding, higher grades and scores on standardized exams, lower rates of grade repetition, higher rates of high-school graduation, lower rates of early teenage sexual activity, lower rates of pregnancy, fewer sexual partners, and lower rates of suicidal thoughts. The fact that the SSDP participants continued to demonstrate improved outcomes over control group subjects at age 21 suggests that the program has a strong, lasting impact on a range of academic, social competence, and delinquency outcomes.

When considering the program evaluation outcomes, it is important to bear in mind that the program has been studied in only one urban metropolitan area (Seattle), which limits the generalizability of findings to other populations. In addition, although well conducted and not subject to any obvious bias, all evaluations of the SSDP to date have been conducted by the program's designers rather than by outside evaluators.

It should be noted that although the parental component of the SSDP was important from the social development model perspective and was considered to be an integral part of the program, parent participation was not mandatory. Research

by J. D. Hawkins and his colleagues in 1999 showed that only 43% of parents attended the parenting workshops, and no assessment was conducted to determine how successful the programs were at teaching parenting skills or whether parents subsequently applied the skills learned in class when interacting with their children at home. Lending positive support to the parental component is a 1992 study by Hawkins and his colleagues that found that children in the full intervention condition (grades 1–6) reported significantly better family management, communication, involvement, and attachment than did control group children. However, none of the evaluations of the SSDP indicate the extent to which the parent component may have played a part in influencing the observed treatment outcomes.

SECONDARY VICTIMS OF HOMICIDE

The two types of crime victims comprise the individual who was directly harmed by the crime and the people who intimately know the primary victim. The latter are referred to as secondary victims, or co-victims. In the case of homicide, secondary victims are those who are not killed by the perpetrator but are the remaining family and friends who are also victimized because their loved one was murdered. It is estimated that each homicide victim leaves behind about three secondary victims who will sustain significant loss and suffering as a result of the murder. Secondary victims of homicide may be parents, spouses/significant others, children, grandparents, or close friends.

Although the primary homicide victim certainly sustains the most devastating outcome of a

murder, secondary victims of homicides are also victimized by the event. In addition to experiencing significant grief from the loss of their loved one, they can also experience anger, posttraumatic stress disorder, and feelings of hopelessness for many years. They can also experience revictimization through their dealings with the criminal justice system. Secondary victims should not only be acknowledged and treated respectfully by the criminal justice system but also educated on the processes necessary to bring the perpetrator to justice. This entry discusses the effects of being a secondary victim of homicide and describes the secondary victims' involvement with the criminal justice system.

Effects of Being a Secondary Victim of Homicide

Even though the actual murder victim suffers the most damage with the loss of their life, survivors also endure the impacts of the death. Unlike other causes of death, such as illness, murder is unexpected and without forewarning, and it immediately changes secondary victims' lives. Suffering for secondary victims of homicide can endure for long periods of time, if not for the remainder of their lives. Children who lose a parent to homicide may externalize their feelings, which may result in conduct disorders. They may also experience problems with self-esteem and difficulties in school.

Secondary victims often feel frustrated because of the lack of resources available to assist them with the emotional and financial problems that result from the death of the homicide victim. Legal stipulations are in place to protect the offender; however, few legal rights exist to protect the victim's family, and they often need to advocate for themselves. Victim support groups do exist. However, they are often managed by victims and mostly rely on soft money and donations to carry out their mission of grief management through support groups, advocacy, and educating the public.

Secondary victims of homicide must also deal with the possible uncertainty surrounding the murder. Homicide is a violent act that does not always have a rational explanation. Several possible motives for homicide include robbery gone wrong, revenge, accidental homicide, or pathological killing by a disturbed offender. Regardless of the reason, if one

exists at all, the secondary victims may struggle with finding meaning in their loved one's death.

Involvement With the Criminal Justice System

Secondary victims may feel victimized a second time by the criminal justice system and the legal process. Because homicide victims cannot assist police in identifying the perpetrator, defend themselves in court, or confront their attacker, secondary victims often take on these roles. Secondary victims are typically prohibited from entering crime scenes where the deceased lies. Although this protects the integrity of the crime scene and allows investigators to do everything they can to collect and preserve evidence to assist in the capture and prosecution of the offender, secondary victims of homicide often feel discouraged that they cannot attend to their loved one.

Secondary victims of homicide may also be questioned about their relationship to the victim and their whereabouts when the murder occurred. This questioning may add to the stress of an already tense situation. However, if there is no known suspect, then those closest must assist law enforcement in narrowing down the suspect pool and ruling out potential suspects because the primary victim cannot speak for himself or herself. Immediate family members and those closest to the primary victim are the most likely suspects, because homicides are most often committed against persons the offender knows. Therefore, whereas it can be offensive or emotionally disruptive to the secondary homicide victim, it is necessary for law enforcement officials to interview and work with the secondary victims to increase their chances of solving the crime. If the police cannot solve the murder, which occurs in about one third of all homicide cases each year, the secondary victims can lack a sense of closure and may suffer emotionally and/or psychologically—more so than they already may have suffered.

The trial, if any, poses another potentially uncomfortable situation for secondary victims. Details of the event and the trauma, torture, or abuse that the primary homicide victim endured are often recounted and can be difficult for the secondary victims to handle. If the crime is particularly disturbing or horrible, then the news media

may sensationalize the situation to sell the story. This can affect the secondary victims adversely, too. Secondary victims may be hounded by reporters. If a long time exists between the murder and the trial, old wounds that may have partially healed may be reopened. Lengthy trials can also prolong the agony for the surviving victims. Hung juries or trials that result in an overturned verdict can prolong the agony. A second trial may ensue, extending the discomfort experienced by the secondary homicide victim and subjecting them to a new trial that may again end in uncertainty, releasing the offender, or a guilty verdict for a lesser charge.

However, a guilty verdict and a prison sentence for the offender may ease some of the suffering for some victims. It is often a relief to the families knowing that the offender is either in prison or will be executed for their crime. On the other hand, if offenders are released from prison on parole or as a result of statutes aimed at reducing prison overcrowding, the secondary victims of homicide can experience additional emotional trauma when the offender is released.

A trial and guilty verdict is hardly sufficient closure for some secondary homicide victims. It may be some comfort to know that the offender will be held accountable for their crime. However, it does not bring the primary victim home. The death penalty may not be the ultimate answer, either. The lengthy process attached to executing a death warrant prolongs the closure process and can revictimize loved ones when, and if, the death sentence is carried out. Because of lengthy appeals processes, death row inmates wait an average of 12 years for the execution to be carried out. The execution of the offender may provide closure and facilitate healing among some secondary homicide victims—if only to end the criminal justice process. Others recognize that the execution of the offender does nothing to bring back the life that was lost.

SERIAL MURDER

In 2005, the Federal Bureau of Investigation (FBI) organized an international symposium in San Antonio, Texas. Approximately 150 of the world's top homicide investigators, forensic psychologists, forensic psychiatrists, criminal psychologists, and other researchers were assembled to discuss and define the phenomenon of serial murder. The purpose of the symposium was to bring together experts in both applied and academic fields who shared a common interest in the ever-expanding scope of serial murder. The symposium was charged with debunking the plethora of myths surrounding serial murder and to give the phenomenon an operationalized definition. The symposium identified several common myths pertaining to serial killers, including that these offenders are all dysfunctional loners, all White males, only motivated by sex, travel and operate interstate, cannot stop killing, insane or evil geniuses, and want to be apprehended.

The symposium reviewed various concepts of serial murder and agreed on several salient factors that should be included in a common acceptable definition. These included factors such as one or more offenders, two or more murdered victims, the murders need to be occurring in separate events and at different times, and finally, the time period between murders separates serial murder from mass murder. As a result, a new definition of serial murder emerged: *the unlawful killing of two or more victims by the same offender(s) in separate events*.

The symposium concluded that there is no *single* identifiable cause or factor that leads to the development of this serial killer, but rather several factors contribute to their development, especially the offender's decision to engage in multiple homicide. The symposium identified several primary motivations for serial murder including anger, criminal enterprise, financial gain, ideology, power, thrill, psychosis, and sex.

Background

Serial murder has been documented in the United States since the early 1800s. However, the incidence and prevalence of serial murder did not come to public awareness until the early 1980s when Robert Ressler, an FBI agent, was summoned by the FBI director. Ressler had been quietly collecting data on serial murder and storing the files in boxes in the basement of the FBI headquarters in Washington, D.C. Known for his persistence when he felt passionate about an issue, no one realized that he was laying the groundwork for one of the most fascinating and horrifying fields of research the world has ever known. The FBI director instructed Ressler to move his data collection out of the basement and officially begin investigating and documenting cases of serial murder. A preliminary review of cases indicated that cases of multiple homicides by sexual predators seemed to be increasing.

In 1984, the FBI appeared before the U.S. Senate to seek funding for the Violent Criminal Apprehension Program (VICAP) by suggesting that as many as 5,000 people per year were believed to be victimized by serial murderers. Although this figure was many times the actual number of annual serial murder victims, the exaggeration did serve to secure significant funding and create one of the most storied units in the history of the FBI. During the mid-1980s, the FBI established the VICAP at its Behavioral Science Unit in Quantico, Virginia (now referred to as the Investigative Support Unit). VICAP is designed to collect detailed information on homicides throughout the United States. Investigators such as former FBI agents Robert Ressler and John Douglas, both pioneers in the investigation and classification of serial killers, collectively interviewed many notorious serial killers in the United States. Ressler and

his colleagues published their findings in *Sexual Homicide*, which became a standard reference text for this form of murder. In addition, the U.S. government continues to develop programs such as the National Center for the Analysis of Violent Crime to focus specifically on repetitive offenders, including serial murderers.

Myths of Serial Murder

Many myths surround the phenomenon of serial murder, including that all serial murderers are intelligent and insane White males who are lust killers with dozens of victims. They act alone as they travel across the United States stabbing, strangling, and beating young women to death. Sexually abused as children, these defective predators cannot stop killing even if they wanted to and secretly hope that someone will catch them. The reality is somewhat different. Approximately 20% of offenders are African American (see case 1), 16% are female offenders (see case 2), and only 2% to 4% are legally insane. Some cases of serial murder are far more instrumental (i.e., killing for money) than expressive (i.e., killing for sexual purposes); most kill fewer than 10 victims; 25% have one or more accomplices; and some use poisons (see case 3) or guns to kill. Most offenders are of average intelligence, stay in the local area to commit their murder series, and many are not trying to be apprehended. Some killers take months or years before they kill again and are very much in control of when and where they will kill. Although some offenders have been sexually abused, far more are found with histories of severe abandonment and rejection by significant others.

Case 1: Chester D. Turner, 1978–1998

Born in Arkansas in 1966, Turner was raised by his mother after his parents divorced when he was 5 years old. The mother relocated to Los Angeles where Turner attended public schools and worked as a cook and delivery man for Dominos Pizza. When his mother decided to move to Utah, Turner stayed in Los Angeles, dropped out of high school, and frequented homeless shelters. He was arrested six times for nonviolent offenses and one assault charge. Turner was concealing much more violence than anyone knew about as he would eventually be

DNA linked to 13 murders of young women in the Los Angeles area. His pattern was almost always the same: Victims were found partially nude, raped, strangled, and left in bushes, vacant buildings, and along roadways. Turner was arrested for the murders while serving an 8-year sentence for rape after Los Angeles Cold Case detectives used DNA to link him to the string of murders. He was convicted of killing 10 individuals as well as an unborn fetus.

Case 2: Olga Rutterschmidt and Helen Golay, 1999–2005

In 2008, Olga Rutterschmidt, 75, and Helen Golay, 77, were convicted of first-degree murder and conspiracy to commit murder for financial gain. The two women had been luring homeless men from a Hollywood church in Los Angeles with promises of food and shelter. Each victim was moved into a comfortable apartment and given care for a 2-year period. Each victim, aged 51 and 73, was also insured for more than \$5.7 million by using multiple insurance agencies. Victims unwittingly signed policies unaware they were signing their death warrants. At the end of 2 years, the time frame for which the insurance policies needed to be uncontested, the victims were drugged, taken to back alleys, and run over to make it seem that they had been killed in hit-and-run accidents. The women, who had spent approximately \$64,000 to care for their victims, collected more than \$2.8 million with their scheme. The 5-year time lapse between the first and second victim was intended to sufficiently separate the two killings so as not to draw attention. However, an investigator who had been looking into the most recent death accidentally overheard another investigator discussing an earlier death that bore striking similarities. Both killers were given life sentences without the possibility of parole.

Case 3: Efren Saldivar, “Angel of Death,” 1988–1998

In 1998, Efren Saldivar, age 28, who was a respiratory therapist for 9 years at Glendale Adventist Medical Center in California, confessed to killing dozens of terminally ill patients during a 10-year period. He claimed to be an “angel of death” who had killed as many as 200 victims from several hospitals where he had worked part

time. Because no independent corroborating evidence was available, police released Saldivar, who later recanted his confession stating that he was depressed and wanted to be executed. An investigation continued into the possibility that Saldivar was telling the truth, but it was not until 3 years after his confession that he was arrested and charged with six murders. Saldivar admitted injecting fatal doses of pavulon, which is a muscle relaxant that suppresses natural breathing, and succinylcholine chloride, which is a drug that also stops natural breathing, into 40 to 50 victims. Later, investigators realized that Saldivar probably had murdered closer to 200 individuals.

Psychopathology in Serial Murder

The term *psychopath* is a nondiagnostic label used to describe persons who possess characteristics at variance with general community standards and practices. People often confuse the popular label *psycho* with psychopath, when actually the terms carry different meanings. Most commonly, the public makes the assumption that someone who is a serial killer must be “psycho” or crazy, out of his mind. Indeed, the behavior may be viewed as “crazy” or bizarre, but in actuality the killer is seldom “crazy” or insane. Psychopaths are generally viewed as aggressive, insensitive, charismatic, irresponsible, intelligent, dangerous, hedonistic, narcissistic, and antisocial. Psychopaths are perceived as exceptional manipulators who can feign emotions to carry out their personal agendas. Without remorse for the plight of their victims, they are adept at rationalization, projection, and other psychological defense mechanisms. The veneer of stability, friendliness, and normality belies a deeply disturbed personality. They are careful to maintain social distance and share intimacy only with those whom they can psychologically control. They are noted for their inability to maintain long-term commitments to people or programs. Although most serial killers are psychopaths or at least exhibit psychopathic characteristics, most criminal psychopaths are nonviolent persons. Indeed, most criminal psychopaths operate as white-collar criminals. However, most serial killers are considered to be psychopaths and exhibit such characteristics as noted in Robert Hare’s description of psychopaths: glibness/superficial charm; grandiose sense of self-worth/narcissism;

pathological lying; conning and manipulative behavior; lack of remorse or guilt; shallow affect; callousness/lack of empathy; failure to accept responsibility for actions; need for stimulation/proneness to boredom; parasitic lifestyle; poor behavioral controls; early behavioral problems; lack of realistic, long-term goals; impulsivity; irresponsibility; and criminal versatility.

The development of a serial killer can be influenced both by genetic predispositions and environmental factors. A lack of nurturing, rejection, abandonment, and/or sexual abuse in early childhood can inflict deep psychological wounds that for some, never heal. Most persons who experience childhood trauma find nonviolent ways to cope with these stressors. Serial killers develop a plethora of behaviors and fantasies that end in the suffering and deaths of others. Eric Hickey’s trauma-control model for serial murder (predispositional factors and facilitators may or may not influence the serial killing process) demonstrates the cyclical nature of serial killers, which suggests that biologically, some persons can be predisposed to violence and that predisposition is exacerbated by childhood trauma. Once the cycle begins, the child develops feelings of inadequacy and low self-esteem that lead to fantasy development. For some, childhood is so traumatic that they experience psychological breaks with reality, or dissociation. For others, their fantasies of control progress into violent fantasies that may be influenced by a variety of facilitators, such as drugs, alcohol, obscene material, erotica, and pornography. Often, these fantasies are of a sexual nature involving paraphilic behaviors that include the suffering and sexual degradation of others. Each homicide committed by the serial killer is followed by events that reinforce the desire to kill. Usually, these events involve loss, rejection, and/or abandonment.

Serial Murder Profiling Strategies

Serial murder has also contributed significantly to the development of several profiling strategies used by investigators and researchers in understanding psychosocial, behavioral, and physical characteristics of offenders and their victims as they strive to improve the effectiveness of serial murder investigations. Successful investigations frequently use several of the following profiling techniques:

Offender Profiling—Law enforcement agencies collect information, often from previous investigations, and form data into general descriptions of persons most likely to commit or be associated with certain types of criminal behavior.

Victim Profiling—Profilers identify the psychosocial and behavioral characteristics of crime victims who are targeted by certain types of offenders.

Equivocal Death Profiling—Also referred to as *psychological autopsy*, investigators gather and use information to explain personal motivations of a person(s) engaged in suicide pacts or deaths where motivations and/or reasons are difficult to determine.

Psychological Profiling—Investigators examine crime scene evidence to determine personality types of those committing the crimes. The purpose is to provide direction to investigators as they develop leads in cases.

Crime Scene Profiling—or *criminal investigation analysis*, originated from the FBI model at the Behavioral Science Unit. Investigators evaluate descriptions of crime scenes physical evidence and criminal behavior before, during, and after the criminal activity, including victim data.

DNA Profiling—Murder cases are sometimes solved using improved techniques in DNA profiling or genetic science. This strategy involves matching DNA from crime scenes to victims and offenders in efforts to identify perpetrators involved in specific crimes.

Geographical Profiling—Also known as *spatial mapping*, this approach combines geography and environmental criminology in connecting crime scenes to offender habitats and locations they use to prey on victims.

Paraphilia Profiling—criminal paraphilia, or sexual gratification using fantasy and/or illegal sexual activity, involves the identification of various forms of paraphilia used by sexual offenders or sexual predators. This involves understanding paraphilia and the role of *relational paraphilic attachment* and how sex offenders attach themselves through fantasy and behavior

with their victims. This may include the use of specific language, behaviors, physical objects, sounds, smells, voices, and many others that are particular to the offender, such as the use of specific recording devices, ligatures, victims, photographs, and weapons that aid in fulfilling the fantasies of the offender(s).

Serial Murder Signatures

Cases of serial killing usually share common characteristics. Serial killers, especially those who are sexual predators, will have distinctive fantasy-driven behaviors that make the crime and the offender(s) unique. Referred to as the *signature*, the personal expression or marking of the offender includes both verbal and physical acts. Serial murderers often create patterns of killing that are customized to fit his or her psychological and physical needs. Also referred to as “calling cards” or “trade-marks,” signatures can also be used by repeat violent offenders such as rapists who are not serial killers. The signature is not required to commit the crime but rather to fulfill the fantasy of the offender. However, sometimes the M.O., or *modus operandi*, employed by the killer to commit his or her crimes becomes part of the signature. For example, sexual predators who are serial killers develop a pattern of stalking behaviors that may be sexualized as the behaviors are carried out. Cary Stayner, who was the Yosemite National Park killer, murdered some of his victims by decapitating them. In this case, the method of killing was also an expression of his paraphilic fantasies, including forested locations where he preferred to kill his victims. These signatures, or *paraphilic footprints*, are extensions of an offenders paraphilic fantasies and aids the offender in actualizing his fantasies.

Investigating Serial Murders

Investigating cases of serial murder often requires multiple resources and personnel. Often, intense public pressure can influence an investigation. Officers, as they create a clear chain of command, need to present a unified front in decision making while avoiding tunnel vision and impulsivity. The symposium in San Antonio, Texas, also noted that sometimes, investigations of serial murder are

“micromanaged” by persons who allow their personal views and egos to cloud effective decision making. Such issues can be avoided with proper command structure and reporting. Collaboration is critical to effect a successful serial murder investigation. Frequently, cases of serial murder involve multiple states that require face-to-face meetings with investigators. Offenders who cross multiple county and state lines to commit their murders become the subject of investigation by law enforcement in each of those locations. Therefore, it is critical that as the investigations develop, a coordinated effort is developed that avoids duplication and redundancy. For example, the symposium strongly recommended that VICAP reports on solved and unsolved murders, attempted murders, and sexual assaults be submitted for inclusion in the VICAP database. Medical examiners should share autopsy information for cases that may be linked and may need to work with other examiners in establishing baseline information.

A significant problem in cases of serial murder is that everyone has an opinion and many are willing to express those opinions publicly. High-profile cases attract media seeking information and insights into investigations that can be intrusive and stymie law enforcement efforts. To that end, the symposium also urged that only experts with proper credentials be used by media to comment on serial murder investigations. Specifically, these persons have access to the complete investigation and can therefore give an informed opinion. However, experts who are not directly involved in an ongoing case can offer general information about serial murder investigations to help the public understand the complexities related to conducting such investigations.

SEVERITY OF VIOLENCE AGAINST WOMEN SCALES/SEVERITY OF VIOLENCE AGAINST MEN SCALES, MEASUREMENT OF

Violence against women has proven to be a construct that is complex to measure and interpret, although many attempts have been made. Linda L. Marshall developed the scales in 1992 in response to her and others' perceptions of shortcomings of the Conflict Tactics Scale (CTS). The original CTS has been criticized for its narrow scope of abusive acts and equal weighting for all events. Marshall developed the instrument specifically to address the shortcomings of the CTS and other instruments, and separate instruments were created for men and women.

Development of Severity of Violence Against Women Scale

After a review of family violence literature, and to establish content validity of the instrument,

Marshall chose items that represent symbolic violence (such as hitting an object), sexual violence, threats of violence (mild, moderate, and severe), and actual physical violence (mild, minor, moderate, and severe). Emotional and psychological violence were not included in the instrument. Initially, female college students rated each of 49 items on nine dimensions of severity and gave each a score of 1 to 10 (scoring key not provided). Marshall calculated a mean severity score, which represented the overall severity of the act, by averaging five of the nine severity dimensions—aggressiveness, abusiveness, threat, violence, and seriousness.

Marshall established construct validity in a three-step process, using data from a collegiate sample ($N = 707$) first, and later with a sample of community women. In the initial study, Marshall conducted an exploratory factor analysis from the data generated by the college women and found that minor violence accounted for the most variance (57%), with the other eight factors accounting for an additional 24% of the variance. Four degrees of severity were included in the factor structure: mild (e.g., shook her), minor (e.g., scratched her), moderate (e.g., slapped her), and serious (e.g., punched her).

In the second part of instrument development, Marshall solicited community participants from a random listing and received usable data from 208 women. The format of the instrument was the same as it had been for the college women, but the community women rated each item only five times, instead of nine times, as the college women had done.

The Severity of Violence Against Women Scale (SVAWS) has been used in many studies since its publication in 1992; has been visible in research worldwide, including Norway, Sweden, and Mexico; and has been translated into Spanish. The SVAWS was used as the comparison measure in the validation of the Propensity for Abusiveness Scale, which was developed in 2001.

Criticisms

Despite its common use in research, the validation process for development of the SVAWS has been criticized for not being sufficiently rigorous. It has been argued that the SVAWS in its current form is

not the best choice for use in research because of faulty content and construct validation procedures.

During content validation, a panel of experts was not used to choose items for the scale, and items were not statistically screened to determine whether they were appropriate to use for factor analyses (construct validation phase). In addition, outside input was not sought for deciding in which category items belonged. For example, Marshall herself determined that a woman being shaken was mild violence, whereas being slapped was moderate violence. From start to finish, only 3 of the 49 original items were dropped. As a result, it is probable that some items on the scale may be inappropriate. Although Marshall stated that the university sample answered questions about the items in nine dimensions, only eight dimensions were provided in the published article, and no rationale was provided for how the dimensions were chosen or why the university and community samples did not answer the same questions about the items.

To establish the construct validity of the SVAWS, Marshall subjected the data to factor analyses, which is an accepted procedure for validation; however, it seems that she decided ahead of time to include a certain number of factors (nine) and provided weak rationale for not adhering to accepted protocol for keeping factors. One of the major functions of a factor analysis is to allow the researcher to eliminate weak items, but in this case, some apparently statistically inconsequential factors were retained, and readers were not provided with statistical evidence to support the unconventional method. Five of the nine factors identified by the author did not meet the accepted eigenvalues or screen test criteria for keeping factors. Instead of customary correlations, more than 1,000 *t*-tests (testing for differences between items) were performed for each factor analysis. Furthermore, the developer did not report making the required statistical adjustment to account for multiple comparisons (adjusted *p* value), which compromises the trustworthiness of the reported results.

Another problem stems from the author's report of reliability work performed on the SVAWS. In the first factor analysis, she reported plausible values for variance accounted for by each factor (the total cannot be more than 100%), but in the second factor analysis, the percentages added up to several hundred percent, which is impossible.

Whether it was a manuscript error not caught by reviewers or incorrect calculations has not been discerned.

Development of Severity of Violence Against Men Scale (SVAMS)

The SVAMS was developed to gauge the effects of women using physical violence against men. The scale contains identical items as for the women's scale. The validation process for the men's scale was similar to that for the women's scale. No instances were found in the literature of its use.

SEX AND VICTIMIZATION

It has been known for some time that a link exists between sex and victimization. That is, gender brings with it differential risks of victimization. It is less understood, however, why that relationship exists. Lifestyles, gender roles, and social constraints unique to the sexes are the leading explanations for why there is a difference in likelihood of victimization. Depending on the type of crime, one is significantly more likely or not to be victimized based solely on his or her sex.

Across a variety of sources of victimization data, it has been shown consistently that men are crime victims more often than women. For overall violent crime, robbery, total assaults, aggravated assaults, and simple assaults, males are more likely than women to be victimized. According to the 2006 Uniform Crime Reporting Program released by the Federal Bureau of Investigation (FBI), men accounted for 79% of all homicide victims. As indicated in Figure 1, males have continuously experienced more violent victimizations than women in the United States. The noteworthy exceptions are rape and sexual assault, for which women are most often victimized.

Figure 1 Violent crime rates by gender of victim (adjusted victimization rate per 1,000 persons age 12 years and older)

Source: Catalano, S. M. (2006, September). *Criminal victimization, 2005*. National Crime Victimization Survey. Bureau of Justice Statistics Bulletin (NCJ 214644). Retrieved from <http://ojp.usdoj.gov/bjs/glance/vage.htm>

Violent victimization against men declined between 1993 (the year of a change in survey methodology by the National Crime Victimization Survey [NCVS]) and 2005 by 57%, from a rate of 60 violent victimizations per 1,000 males to 26 violent victimizations (Figure 1). For women, the decline was slightly greater (58%) from 41 to 17 violent victimizations per 1,000 females (Figure 1). It should be noted that all figures from the NCVS are for persons ages 12 years and older; hence, certain crimes such as child abuse against those younger than 12 is not represented in the official statistics.

The 2005 iteration of the NCVS provides another example of gender differences in victimization: For violent victimization, women are most often victimized by nonstrangers (people they know), whereas men are most often victimized by strangers. Regardless of the type of violent victimization, this victim-offender relationship holds constant. For example, in examining all violent crimes, 64% of women were victimized by nonstrangers, whereas 54% of men were victimized by strangers. Delving deeper into the victim-offender relationship, 39% of the violent victimization of women by nonstrangers was perpetrated by friends or acquaintances, and 18% of violent victimizations were committed by intimate partners. For men, 36% of nonstranger victimizations were carried out by friends or acquaintances.

It has been argued that the NCVS underestimates rape in its annual victimization estimates. For that reason, other sources can be examined to understand more accurately the true extent of rape—namely the National Violence Against Women Survey (NVAWS). It is difficult to compare estimates of the NCVS with the NVAWS because of differences in measurement and methodology. However, the NVAWS still provides valuable information on a range of victimizations. The survey's findings suggest that 17.6% of women and 3% of men in the sample experienced a completed rape during their lifetime. In the 12 months preceding the survey, 0.3% of women and 0.1% of men in the sample experienced a completed rape.

The NVAWS provides other important information pertaining to the issue of sex and victimization. Notably, women experienced more partner violence than men (25% vs. 8%). Additionally,

violence against women was usually committed by intimate partners, with 76% of physically victimized women (since the age of 18) being injured by a spouse, former spouse, domestic partner, or date. Women were more likely than men to be injured during an assault, with 32% of women and 16% of men who were raped (since the age of 18) being injured during their most recent rape. Finally, the NVAWS indicates that women were more likely than men to be the victims of stalking during their lifetimes (8% vs. 2%).

According to the NCVS, men and women respond differently to victimization as well. Females are more likely than males (54.6% vs. 42.4%) to report their violent victimizations to the authorities. Conversely, women are slightly less likely to report their property victimizations to the police than men (39.2% vs. 40.0%). The response to victimization, especially sexual victimization of women, has important implications for the risk of future victimization. It has been documented that being sexually or physically abused in childhood or adolescence is a good predictor of future victimization, especially for women who experienced both types of victimization.

It is clear that women and men are victimized at different rates depending on the type of crime. Also, consequences of and responses to that victimization depend on the crime for males and females. Explanations for gender differences in victimization vary and include routine activities, lifestyles, social constraints, and gender role differences between the sexes. Furthermore, feminist scholars have suggested that the sexual victimization of women is enabled by male dominance, societal attitudes, and a tolerance for such crimes.

SEXUAL ASSAULT NURSE EXAMINER (SANE)

A Sexual Assault Nurse Examiner (SANE) is a registered nurse who has undergone specialized training to identify injuries and to provide comprehensive care to victims of sexual assault. The registered nurse participates in criminal investigations by documenting evidence and/or testifying in court. Forensic nursing uses the nursing process to support legal concerns as it is the intersection between the medical field and the judicial system. Living forensics involves unrecognized or unidentified trauma and the recovery of evidence from live clients. Forensic nurses seek the truth by identifying, collecting, protecting, and documenting evidence. This process involves public health, as it also addresses biological and environmental threats to the health and safety of the community.

Victims and perpetrators are examined by nurses for treatment of injuries. The nurse is in the

ideal position to gather information and physical evidence, as the nurse is often the first point of contact in the health care arena. However, nurses must also be able to recognize injuries, because every injury, illness, or death can possibly have forensic implications. The identification of victims can assist in preventing additional injury or death from recurring cyclical violence.

Sexual assault is one of the most frequently committed crimes in the United States, and it is committed most frequently against women. Since 1992, the Joint Commission on Hospital Accreditation (JCAHO) has required ambulatory facilities to have protocols for rape victims. Since 1997, JCAHO has recognized the need to have facilities develop and train health care staff to identify possible victims.

Education

A registered nurse can be educated as a SANE to identify sexual assault and injury more accurately and then to give comprehensive care to the victims. The SANE has additional education that includes a minimum of 40 hours of didactic instruction, observation with an advocacy program, courtroom observation, and forensic laboratory observation. This additional education gives the registered nurse a greater ability to identify trauma. While doing observations, the SANE also works with a preceptor to develop clinical skills. After completion of the above-mentioned training, the SANE is credentialed. When a SANE has practiced for 2 years, he or she has the opportunity to sit for certification in either the adult or pediatric arena. This certification is awarded through the International Association of Forensic Nurses (IAFN). The role of a SANE is to offer comprehensive care to the victim, and therefore, care includes a variety of patient needs, such as assessment, diagnosis, implementation, and evaluation. This role is defined by the IAFN.

Examination Process

The SANE is responsible for completing the entire sexual assault examination. After identifying a victim of sexual assault, an additional evaluation is initiated. Physical assault may include genital or nongenital trauma. Thus, care may begin with

medical care to protect the patient's airway, dress wounds, or suppress bleeding. Along with caring for acute medical problems and collecting significant health history information, this examination includes crisis intervention as the SANE considers the possibility of psychological trauma. Therefore, an advocate is recommended for counseling support for the possible chronic impact of post-traumatic stress disorder (PTSD), rape trauma syndrome, and suicide risk.

To continue to offer the best care to the victim of sexual assault, the SANE needs to evaluate the risk for sexually transmitted infections and offer prophylactic treatment. Providing a resource for confidential/anonymous HIV testing is important. Pregnancy risk should be assessed. A resource for prevention of pregnancy medication should be provided if the patient has been examined within 72 hours of assault. Information on hepatitis B, referral for follow-up care, and vaccination should also be available.

Interviewing the patient is the best way for the SANE to begin the medical/forensic examination. The SANE listens to the patient's history of the assault, using this narrative history as a guide for the physical examination. The patient history is documented in the patient's own words. Therefore, it is documented in the record using the patient's terminology and vernacular, quoting the victim's own words.

A complete head-to-toe assessment is conducted with a focus on inspection to identify and then treat injuries. The SANE is looking for forensic evidence. This evidence is collected by swabbing, debris collection, or photo documentation. The evidence may also include the victim's clothing, at the least the clothing from the primary drainage site. The collection of evidence may vary from state to state; therefore, the National Protocol may be a guide. Evidence collected may include swabs from all orifices. Also, a swab from the victim's skin that may have body fluids from the perpetrator is collected. In addition, the SANE collects buccal (inside the mouth) swabs or blood to identify the victim's DNA. Furthermore, debris or foreign material from the victim or victim's clothing is collected. In addition, pubic and head hairs are collected. Fingernail scrapings may also be necessary if, according to the victim's history, harm was incurred on the perpetrator. Finally, blood and

urine may be collected from the victim for drug facilitated sexual assault. The pattern of injuries is documented through body diagrams and photos. All physical findings need to be documented objectively on appropriate forms.

The SANE also shines an alternative light source over the victim's body to look for body fluids that fluoresce. Swabs are then taken of these fluoresce areas, dried, sealed, and identified on the swab container. The identification includes where the swab was collected and what the body fluid stain may be.

All external injuries should have a minimum of two photos, one with a ruler and one without. Using a ruler documents the size of the injury, and a photo without a ruler documents that no cover-up of the injuries occurred. Genital injury photos should be documented with the amount of magnification used. Using objective medical descriptive terminology, the examiner describes the injury. It is helpful in documentation of genital injuries to use a clock face as a guide for location of injuries, with 12 o'clock always toward the victim's anterior superior genitalia.

Evidence Collection and the Criminal Justice System

Evidence collection is one of the main goals of a medical forensic examination. However, it needs to occur alongside preparing documentation and maintaining chain of custody. Each piece of evidence needs to be packaged separately in paper or cardboard sealed with evidence tape and identifying information. The chain of custody needs to be documented from the collection to all handling transfer and storage of evidence documented.

The SANE interacts with law enforcement either before or after the examination as they work together to offer the best care and investigation to the victim. A multidisciplinary approach to the care of a sexual assault victim is best and most comprehensive. The team includes law enforcement, prosecution, advocacy, SANE, and forensic laboratories. Because the SANE is an integral part of the investigation of the crime, they can be called to court to offer testimony as either a fact or an expert witness. This testimony covers the care given the victim, the evidence collected, and possibly the opinion of evidence found.

The ultimate goal is for all victims of sexual assault to be given a careful and consistent evaluation by well-educated examiners. To ensure this comprehensive care, the SANEs are active in educating health care and community agencies on the best care for these victims, that being, access to specially educated and clinically prepared SANEs and the multidisciplinary team of law enforcement, prosecution, advocacy, and forensic laboratories.

SEXUAL ASSAULT RESPONSE TEAM (SART)

Sexual assault is a public safety issue that greatly impacts society on multiple levels. By the mid-1970s, sexual assault response teams (SARTs) began to develop as a way to coordinate and enhance various systems of response, including medical treatment, criminal/judicial processes, and support services. For victims of sexual assault, barriers to the criminal justice system are

overwhelming in terms of poor police response, the dismal number of cases prosecuted, and the low percentage of sexual offenders being indicted and held accountable for their crimes. Research has demonstrated that most victims who reported to the police believed that rapists had more rights, thought the system was unfair, felt that victims' rights were not protected, and experienced revictimization. In efforts to treat and collect evidence from sexual assault survivors with more sensitivity and effectiveness, some communities have established SARTs.

SARTs increase the quality of care for survivors and reduce the secondary trauma survivors often experience as they navigate these related response systems. SARTs exist in many different forms and in many different contexts. Some SARTs respond together in the immediate care of the survivor at the time of the sexual assault forensic examination. The response of these SARTs is activated when a sexual assault victim comes into contact with the system of response, typically by seeking medical treatment or legal action. Other SARTs are composed of individuals who work independently but meet regularly to assess and evaluate the overall system of response, such as general policy and legislative review.

The benefits of SARTs extend beyond the direct victim. Community-based teams that include a Sexual Assault Nurse Examiner (SANE) program benefit the health care system, in particular hospital emergency rooms. Although many physicians are reluctant to collect sexual assault forensic evidence because of the possibility of legal involvement, the existence of this type of SART program provides sexual assault victims with specialized medical treatment. It is also part of a SANE's training and responsibility to provide expert witness testimony, which greatly supports the roles of law enforcement officers and prosecutors. SARTs enable all those agencies responsible for prosecuting rape cases and holding perpetrators accountable to coordinate their efforts as they build the strongest case possible for prosecution. Campus-based SARTs began to increase soon after the Crime Awareness and Campus Security Act was passed in 1990. This legislation, which was renamed the Clery Act, requires campuses to employ strategies to protect the rights of sexual assault victims. SARTs often serve as one such

strategy employed by college campuses to comply with this mandate and in meeting the needs of college students, who are at highest risk for sexual victimization.

Although SARTs differ based on the community they serve, certain common characteristics are shared by most teams. The National Sexual Violence Resource Center published the *Report on the National Needs Assessment of Sexual Assault Response Teams* in March 2006. The reported findings were compiled from survey responses from agencies that represent victim services, health care, law enforcement, statewide coalitions, military, higher education, prosecution, social services, and civil legal. According to the report, most SARTs have been in place for 3 or more years, with the largest percentage of teams having been in existence for 3 to 5 years. Of all responding teams, the “oldest” SART was created in 1974. Most SARTs do not have an administrator/coordinator and do not receive funding. Between 72% and 87% of the respondents reported that they have prosecution agencies, forensic examiners, law enforcement agencies, and support and/or advocacy agencies as core members of the multidisciplinary SART. In addition to the core agencies on their SART, respondents also indicated organizations with whom they currently collaborate and agencies with whom they would like to collaborate. SARTs were most likely to collaborate with hospitals and law enforcement agencies (80% and 78%) and were least likely to collaborate with Indian Health Services and tribal agencies, alternative medicine professionals, and chaplains (less than 10% each). SARTs are most interested in collaborating with faith-based organizations (31%), groups that support underserved populations (28%), and organizations focused on individuals with disabilities (26%). Additionally, SARTs were interested in collaborating with individuals such as legislators (25%) and judges (30%), who influence and enforce policies. SARTs have multiple tasks including quality assurance, participation in ongoing training, and the development of materials to support and guide their work as a team. In conducting their business, SARTs typically meet monthly or quarterly.

SEXUAL HARASSMENT

Sexual harassment is a type of workplace discrimination that is prohibited by the Civil Rights Act of 1964 and is therefore a violation of federal law. In general, sexual harassment includes hiring and management practices that discriminate against a worker based on the employee's sex, and it includes unwanted physical or verbal sexual attention from colleagues or supervisors. The act covers all employers with 15 or more employees, which include governmental agencies and labor organizations. Sexual harassment imposes an uncomfortable work environment on the recipients and

can affect worker productivity and morale, while creating legal risk exposure for employers. Extreme forms of sexual harassment include rape, sodomy, and aggravated assault, thereby encompassing criminal activity that has social impact beyond the workplace.

Definitions: Legal, Social, and Behavioral

In Title VII of the Civil Rights Act of 1964, employers are prohibited from practicing discrimination against workers based on their sex, including refusal to hire or otherwise adversely affecting the employee's status. The U.S. Equal Employment Opportunity Commission (EEOC) details the elements of sexual harassment and includes unwelcome sexual overtures or requests that hinder an employee's ability to work effectively. Sexual harassment occurs when acceptance of sexual conduct (either verbal, nonverbal, or physical) is made a condition for getting or keeping a job (either tacitly or directly), when employment decisions are based on one's rejection or acquiescence to such conduct, or when verbal or physical sexual acts create an offensive atmosphere of hostility or intimidation for the employee.

The offender and victim may be of either sex, and the offender need not be the opposite sex of the victim. Furthermore, the harasser does not have to be the victim's boss but can be a co-worker, a representative of the employer, or even a nonemployee. Conduct that ranges from unwelcomed sexually charged comments or jokes up to physical sexual contact and even assault may be considered sexual harassment. Certain types of sexual favoritism are also prohibited, and a workplace culture in which widespread favoritism is based on the granting of sexual favors would also be considered a hostile work environment. Employers are also prohibited from retaliating against workers who file claims of sexual harassment against them.

The EEOC recognizes two main categories of sexual harassment: *Quid pro quo* and harassment stemming from a *hostile work environment*. *Quid pro quo* sexual harassment was recognized by a federal district court in *Williams v. Saxbe*, 413 F. Supp. 654 (D.D.C. 1976), and refers to situations in which the employer demands acquiescence to unwanted sexual advances or otherwise sexually oriented physical or verbal conduct as a condition for obtaining or keeping some occupational benefit.

In *Saxbe*, the D.C. district court ruled that such actions constituted an "artificial barrier" to employment and were therefore discriminatory under Title VII. Thus, a supervisor who pressures an employee for sex in exchange for a favorable performance evaluation has committed *quid pro quo* harassment. It can also extend to other management decisions made about the employee if based on his or her submission to the conduct.

A hostile work environment is a workplace culture that is pervasive with repeated verbal and physical abuse of a sexual nature. The offensive workplace may be created by anyone in the place of business, including co-workers, students, or customers. This type of harassment was first recognized in the 1986 U.S. Supreme Court ruling in *Meritor Savings Bank v. Vinson*. In that case, the court ruled that in determining whether a workplace was hostile, one needed to consider the overall frequency, intensity, and pattern of harassment, and that one instance of the conduct would not support a charge of a hostile workplace. An investigation would need to discover a pervasive pattern of unwanted sexual imagery, jokes, comments, or other behaviors to determine whether the workplace was offensive.

Legal distinctions aside, other scholars have formulated and identified different elements, such as gender harassment, sexual seduction, sexual coercion, sexual imposition, and sexual assault, as various types of harassment that may be ordered into a continuum of progressively harassing behaviors. Gender harassment refers to the systemic degradation or abuse of a person based on his or her sex. An example of gender harassment might be disparaging comments about a woman's menstrual cycle or leaving women's underwear around a female employee's workstation. Sexual seduction (despite the romantic connotations of the word) refers here to unwanted sexual attention, such as repeated requests to date despite being made aware that the victim is not interested or repeated unwanted sexually based comments.

Sexual bribery/coercion include harassing behaviors that present a *quid pro quo* dilemma, as mentioned, in which the harasser inflicts a dilemma on the victim in which the victim must submit to unwanted sexual behaviors or acts or face negative workplace consequences. Sexual imposition would encompass overtly assaultive criminal acts. Scholars

who recognize these dimensions of sexual harassment maintain that any of them may range from minor to severe criminal harassment.

Other academic definitions of sexual harassment are closely tied to these from the EEOC, including unwelcome sexual attention (to include leering, teasing, jokes, or comments directed toward the victim's sexuality; unwelcome pressure for dates or sexual favors; fondling, touching, or pinching; and implied retribution for not cooperating with the harassment).

Social conceptions of sexual harassment related to the creation of hostile work environments and the quid pro quo sexual exchange pressures mentioned above also encompass the power differentials between the victim and harasser, or overt or covert hostility against one's gender; these differentials are reinforced by the implied or explicit threat of retaliation. Landmark court cases on sexual harassment documented cases of male employees hiding pornography in the female victim's toolbox, urinating in their water bottles, sustained requests for oral sex, threatening to cut off a woman's breast, forcibly holding a victim over a stairwell's 30-foot drop, and other intensive abuse and criminal activity.

Many scholars maintain that sexual harassment is based on the same continuum as other forms of sexual aggression, so harassment that includes criminal activities such as rape or assault are simply extensions of the same kinds of attitudes and personality as less severe forms of harassment.

Prevalence

It is difficult to track the true prevalence of sexual harassment because many women do not report it for a variety of reasons, which include the fear of retaliation or because they do not always recognize the offending behaviors as such. As one source points out, people tend to have differing ideas about what sexual harassment means. When looking at international data, the problem becomes exacerbated because there is no universal definition of sexual harassment.

In the United States, the EEOC reports that between 1997 and 2007, between 12,025 (2006) and 15,889 (1997) Title VII sexual harassment charges had been filed with the commission. In 2007, the EEOC received 12,510 charges, and investigation disclosed that in 5,273 (45.5%) cases,

the investigation did not garner sufficient evidence to believe that discrimination occurred. In all, 3,013 (30.3%) charges were considered to be merited and the remaining cases were categorized as "administrative closures," in which the case was closed because of reasons such as the charging party could not be located, rejected full relief measures, or withdrew the complaint. In the 1997 to 2007 time frame, more than 80% of the charges were filed by women, and the total annual relief payouts ranged from \$30.3 million (1998) to \$54.6 million (2000).

Academic studies into sexual harassment incidence have disclosed widely ranging results and have been hampered in some cases by sampling design or by varying definitions of what constituted sexual harassment. However, research indicates that more than half of surveyed women reported being subject to some form of potentially sexually harassing behavior at work, although only a quarter of them would label the conduct as "sexual harassment." This indicates that although women may feel subjected to harassing conditions, they may be reluctant to label the behaviors as such.

Nonacademic surveys also vary widely, reporting results of sexual harassment among women between 42% and 90%. Whatever sources one reviews for sexual harassment incidence, it is likely that the true prevalence will remain underreported.

Historical Perspectives

The concept of sexual harassment originated from 1970s feminist writings about the ongoing workplace sexual intimidation and coercion faced by women. Feminist scholars at the Massachusetts Institute of Technology (MIT) brought the attention of the university's administration to issues of gender inequality in the workplace, and MIT was among the first institutions to recognize the harmful effects of sexual discrimination in the workplace. A wave of 1970s academic feminists and authors popularized the foundational issues of sexual discrimination and violence against women, and they raised initial public consciousness about the challenges faced by women in the workplace and elsewhere in society.

The 1972 creation of Equal Employment Opportunity Commission by the U.S. Congress provided a tool to enforce violations of the Title VII laws, including sexual harassment. Despite this

action, victims of sexual harassment were left with limited options. They could win back pay or reinstatement (if forced to leave) to the same hostile job environment, but could not win punitive damages from the employer. They were often compelled to continue working under the same offensive conditions. Also at that time, Title IX of the Educational Amendments of 1972 was passed, which outlawed sexual discrimination at academic institutions, both in the classroom as well as in athletics. In 1991, Congress amended the Civil Rights act to provide for pain and suffering damages for sexual harassment victims if they could demonstrate sufficient malice or indifference on the part of employers.

Also in 1991, Anita Hill's testimony before the Senate Judiciary Committee during the hearings on Supreme Court nominee Clarence Thomas did much to heighten awareness on the issue of sexual harassment. Hill, who is an Oklahoma law professor, accused Thomas of committing harassing behaviors when she worked for him years earlier at the EEOC. Among the accusations made by Hill were that Thomas harassed her with inappropriate sexual commentary and pornography after she refused to date him. Thomas denied the allegations and was eventually narrowly confirmed for the Supreme Court seat, but the dispute attracted intense media coverage and raised public awareness of the issue.

President William Clinton also faced allegations of sexual harassing behaviors during the 1990s, most notably involving White House intern Monica Lewinsky and, earlier, Arkansas state employee Paula Jones. These instances generated massive media coverage and eventually ended with wide-ranging political and cultural ramifications. Furthermore, the 1990s saw an increasing output of scholarly journal articles dealing with sexual harassment and academics, detailing studies and reviews of the problem as faced by female faculty members by colleagues and students alike. Finally, a 1999 International Association of Chiefs of Police study states that between 68% and 86% of female officers report having been subjected to sexually harassing behaviors. It may be fair to state that the 1990s decade clearly demonstrated that sexual harassment is not limited to trade occupations but is observed in other professions and jobs as well.

It is important to remember that although most sexual harassment allegations are made by women, men can also be victimized, and by other men. In the case of *Oncale v. Sundowner Offshore Services, Inc.* (1998), a male oil-rig worker named Joseph Oncale claimed that he was sexually assaulted and threatened with rape by his male co-workers while working on a rig platform in the Gulf of Mexico. Oncale alleged that he was subject to ongoing sexual commentary and that the physical assaults included having a bar of soap shoved between his buttocks. Although Oncale complained, the company attempted to downplay the activity as hazing or male-on-male horseplay, but the U.S. Supreme Court ruled that same-sex harassment is actionable (even if sexual gratification by the harassers is not evident).

Policy Implications: Prevention and Response

Sexual harassment claims filed against employers can be costly, and the resulting media coverage or word-of-mouth anecdotes can damage the reputation of a company or agency when harassing environments are allowed to continue. Furthermore, sexual harassment can result in employee turnover, poor morale, and lost productivity. Therefore, employers from the U.S. military to universities to multinational corporations to small businesses have enacted sexual harassment guidelines, policies, and training to prevent and respond to workplace discrimination. Moreover, the EEOC requires that employers take reasonable actions to prevent sexual harassment.

Because Title VII does not forbid all sexual content in the workplace, the EEOC advises that policies should focus on the definition as set forth in its own guidelines, specifically the quid pro quo and the hostile environment categories. Understanding the nature of the harassment can also determine the amount of employer liability.

In investigating cases of sexual harassment, the EEOC recommends that both the charging party and the accused are questioned carefully to determine whether the behavior occurred, whether it was unwelcome, and whether there is a sexual aspect to it as defined by the commission. In determining credibility, the investigator should check internal consistency of the employees' statements, corroborating facts and circumstances, as well as

all other evidence. The victim's statement alone may be enough to sustain a charge, in light of all other factors.

In determining whether a workplace is considered to be "hostile," the investigator considers whether the charged behaviors establish a sustained, pervasive, frequent set of behaviors. Also considered is whether more than one person is often subjected to the behaviors. The degree of intimidation is important in making this determination, because occasional flirtations or vulgarities are probably not enough to rise to the level of a hostile workplace. Although infrequent verbal offensiveness may not be considered sexual harassment, the EEOC does advise that one-time fondling or intimate touching would certainly be.

Courts have offered conflicted rulings on issues of overall language, actions, and environment ("girlie" magazines or posters, habitual rough language that is used as a general means of speaking), and individual cases are weighed against the "reasonable person" standard. This means that one would examine the behaviors in light of how a reasonable individual might view them: For example, a charge that complained that a male employee held a door open for a female employee would most likely fail under this standard. The EEOC also recommends that employers have some sort of internal grievance procedures to allow the employee a format to pursue his or her claim and to establish an environment of effective redress before going to court.

Because sexual harassment complaints can demand a great deal of time and effort to investigate, employee policies may warn against filing frivolous, malicious, or hypersensitive charges.

Other experts point out that a key element to preventing sexual harassment is to distribute a statement of employer policy, in which a high-ranking official explicitly prohibits the conduct. Employer policies are advised to define the conduct carefully along EEOC guidelines and to emphasize the aspect of the law that expressly forbids retaliation against grieving employees. Workplaces generally also include disciplinary actions, including termination, which may be taken against employees who are found to have committed sexual harassment. The investigation and reporting procedures should be clear, with several reporting agents available (to prevent the conflict of the sole person

in charge of receiving complaints also being the one who might be charged). The investigation procedure should allow for a neutral, systematic gathering of facts that allow the charged persons as well as the plaintiff the opportunity to respond to all relevant questions. These sources add that timeliness of reporting standards be part of the policy, to prevent old incidents from being dredged up for the first time in a complaint. Old complaints make it more difficult for the company to address the issue, and more difficult to investigate. The final decision should be based on the totality of facts and circumstances gathered in the case and not solely on one particular point.

However employers enact their policies, policies are advised to be crafted in accordance with EEOC guidelines and to be well disseminated so that all employees have access to them and that victims are encouraged to report illegal activities. Although the confidentiality of witnesses or complainants may be assured to the extent that is allowed, it is possible that it may be later breached. This is particularly so in forcible, assaultive, or otherwise criminal conduct that is reported to law enforcement and becomes merged into the criminal justice system.

Sexual harassment can be a controversial issue for many reasons, whether it is because ongoing, intensely abusive environments that include criminal actions may have been allowed to victimize workers, or because frivolous or false claims can have dire consequences against those who are wrongly accused.

Human interaction is always an unpredictable milieu and is subject to emotions and differing personalities, and the sexual harassment laws and policies may not always be easy to apply or enact. However, the same can be said of any set of laws that seek to govern human behavior. Because sexual harassment includes criminal conduct, it is properly regarded as part of the spectrum of aggression, violence, and crime, and it is not just a workplace problem.

SEXUAL HARASSMENT, MEASUREMENT OF

Recent accounts of sexual harassment have been widely publicized, with both the accused and the accusers receiving much scrutiny. What is interesting, however, is that before the 1960s, sexual harassment per se did not exist. This is not to say that people were not experiencing unwelcome sexual attention at their place of employment or at school; it simply did not have a formal label.

The first step, then, that occurred in labeling sexual harassment came through workplace law and the courts. This entry defines both workplace and school-based sexual harassment and discusses the measures of each.

Defining Workplace Sexual Harassment

Sexual harassment in the workplace is a form of sex discrimination that is prohibited by Title VII of the Civil Rights Act of 1964. Applying to employers who have 15 or more employees, the federal government, employment agencies, and labor organizations, it protects employees from sexual harassment. According to federal law (CFR 1604.11), the definition of sexual harassment is

Unwelcome sexual advances, requests for sexual favors, and other verbal or physical conduct of a sexual nature constitute sexual harassment when (1) submission to such conduct is made either explicitly or implicitly a term or condition of an individual's employment, (2) submission to or rejection of such conduct by an individual is used as the basis for employment decisions affecting such individual, or (3) such conduct has the purpose or effect of unreasonably interfering with an individual's work performance or creating an intimidating, hostile, or offensive working environment.

Within this definition of sexual harassment are two specific types—quid pro quo and hostile environment. Parts 1 and 2 of the definition represent quid pro quo harassment. This type of sexual harassment occurs when employment decisions are based on an individual's response to sexually harassing behaviors. Hostile environment sexual harassment, which is described in part 3 of the definition, is conduct that negatively impacts work performance or creates a hostile working environment. Although two types, both quid pro quo and hostile environment harassment, can occur together—for example, a person does not wish to engage in sexual conduct with her boss and after rejecting such conduct, her work environment becomes increasingly hostile with veiled threats of firing for noncompliance.

Measures of Workplace Sexual Harassment

One avenue of redress that victims of workplace sexual harassment have is to report their experience to the U.S. Equal Employment Opportunity Commission (EEOC). Importantly, much like other types of sexual victimization such as rape and sexual assault, victims seldom formally report their sexual harassment. Because formal reporting sources are likely underestimating the amount of sexual harassment that occurs, other attempts at uncovering the true extent of sexual harassment have been taken. As early as 1980, sexual harassment was defined and classified into several different types of behaviors that included gender harassment, seductive behavior, sexual bribery, sexual coercion, and sexual imposition or assault.

To measure sexual harassment, the Sexual Experiences Questionnaire (SEQ) was developed in 1988 by Louise Fitzgerald and her colleagues. Designed to measure the five classes of sexual harassment identified by Frank Till via multiple items for each class, the SEQ uses behaviorally specific questions that ask whether a person has experienced certain behaviors at work without including the term *sexual harassment* in the question. One question included in the SEQ is "Have you ever been in a situation where you actually experience negative consequences for refusing to engage in sexual activity with a co-worker?"

The SEQ has been widely used in a variety of settings, but it should be noted that the original questionnaire has been revised numerous times. Although the original version had five factors, more recent versions used by the original authors are based on a three-factor model—sexual coercion, gender harassment, and unwanted sexual attention.

Other measures have been designed to tap into behaviors identified by the EEOC that have been developed. In fact, the Inventory of Sexual Harassment was designed by James Gruber to reflect the guidelines of the EEOC. The Inventory of Sexual Harassment covers three general categories of sexual harassment: verbal requests, sexual remarks/comments, and nonverbal displays.

The U.S. federal government has also taken on itself to measure the extent of sexual harassment among federal workers. To do so, the U.S. Merit Systems Protection Board has conducted multiple

surveys, beginning in 1980 and then again in 1987 and 1994, that included more than 13,000 respondents. To determine incidence, respondents were asked whether they had experienced any of seven types of uninvited sexual attention during the previous 24 months.

Defining School-Based Sexual Harassment

Not only is sexual harassment prohibited in the workplace, it is also disallowed in school settings. Under Title IX of the 1972 Education Amendments, sex discrimination is prohibited in educational programs or activities that receive federal financial assistance or in institutions where students receive federal financial aid. Enforced by the Office of Civil Rights (OCR) housed in the Department of Education, the definition employed by this office includes peer-to-peer sexual harassment. It defines sexual harassment as

Unwelcome conduct of a sexual nature. Sexual harassment can include unwelcome sexual advances, requests for sexual favors, and other verbal, nonverbal, or physical conduct of a sexual nature. Sexual harassment of a student can deny or limit, on the basis of sex, the student's ability to participate in or to receive benefits, services, or opportunities in the school's program. (p. 2)

Sexual harassment, which is a form of sex discrimination, comes in two forms. Quid pro quo harassment involves unwanted sexual harassment and/or advances that involve the promise of benefit. Such harassment may involve a request by a teacher to a student in exchange for grades. According to Catherine Hill and Elena Silva, hostile environment harassment, which is the second type of sexual harassment, occurs when harassing sexual conduct is so "severe, persistent, or pervasive that it limits a student's ability to participate in or benefit from educational activities" (p. 7). Schools and universities can be held liable under Title IX for student-to-student and teacher-to-student sexual harassment. The OCR receives about 5,000 complaints a year, 10% of which are regarding sex discrimination. Most of these complaints deal with sexual harassment and refer to

incidents occurring to individuals in grade school (K–12), with slightly less than half coming from students in college. The courts have ruled that colleges, universities, and K–12 schools can be liable for the sexually harassment of students under Title IX.

Measurement of School-Based Sexual Harassment

Measuring school-based sexual harassment is somewhat different than the ways in which sexual harassment at work is measured. Students are generally asked whether they have experienced a range of behaviors at the hands of students, teachers, or other employees of the school. The most comprehensive study of school-based sexual harassment was undertaken by the American Association of University Women (AAUW) in 1993. Using behaviorally based questions, students were asked, “During your whole school life, how often, if at all, has anyone (this includes students, teachers, other school employees, or anyone else) done the following things to you when you did not want them to?” A list of 14 items was then provided, which included, among other things, made sexual comments, spied on you, flashed you, pulled clothing down, and forced you to do something sexual.

The AAUW also conducted a study of sexual harassment on college campuses. According to Hill and Silva, sexual harassment was defined in the survey, as “unwanted and unwelcome behavior which interferes with your life. Sexual harassment is not behaviors that you like or want (for example wanted kissing, touching, or flirting)” (p. 6). Later in the survey, a list of 15 behaviors was given, and respondents indicated whether they had personally experienced them in different school contexts. The list of behaviors ranged from having sexual comments made to being forced to do something sexual, other than kissing. About 60% of college students reported experiencing sexual harassment, with receiving sexual comments, looks, or gestures, as being the most common behavior experienced. Most sexual harassing incidents were noncontact forms of harassment.

This recent measurement tool is instructive in that its approach improves on some limitations of

earlier work. It used behaviorally specific questions, prompted respondents to think of behavior that is unwanted and unwelcome, included both illegal behaviors and behaviors that may be negative but not necessarily illegal, and instructed students to consider behaviors during class and other college-related events, such as school-sponsored activities. Also important, it includes computer-based and online behaviors that, until recently, were not included in measurement tools.

CFR 1604.11: <http://www.gpoaccess.gov>

SEXUALLY TRANSMITTED DISEASES AND SEXUAL VICTIMIZATION

Sexually transmitted diseases are infections often transmitted by sexual contact between individuals. Sexually transmitted diseases most often are transmitted via vaginal intercourse (penetration of the vagina by the penis), anal intercourse (penetration of the anus by the penis), and oral sex (oral-genital contact). Sexually transmitted diseases can be transmitted by other means, however, including nonsexual means (e.g., during childbirth or through needle sharing). Other potential modes of transmission include kissing, rubbing of the genitals, and touching of the mouth or genitals. Sexually transmitted diseases include bacterial infections such as gonorrhea, chlamydia, and syphilis; viral infections such as human immunodeficiency virus (HIV), hepatitis B, and human papillomavirus; and trichomoniasis, which is caused by a single-celled protozoa. The consequences of untreated sexually transmitted diseases vary by infection type but can include pelvic inflammatory disease, infertility, cervical cancer, increased vulnerability to HIV transmission, and even death.

Sexually transmitted diseases associated with sexual victimization can occur among male and female victims, including children, adolescents, and adults. Sexual victimization most often includes sexual activity obtained by force, threat, or that occurred when an individual was not capable of consenting. The latter can include sexual activity with a child, an individual with limited mental capacity, or an individual who was unconscious or impaired as a result of ingestion of substances. The full spectrum of sexually transmitted diseases has been documented after sexual victimization, including hepatitis B and HIV.

Prevalence of Sexually Transmitted Diseases After Sexual Victimization

Several factors affect the likelihood that an individual who experiences sexual victimization will acquire a sexually transmitted disease. These factors include the prevalence of sexually transmitted diseases in the community, whether a male assailant uses a condom, the number of assaults, the number of assailants involved, the type of sexual acts performed, whether the victim experiences a genital or anal injury, and whether a male assailant ejaculates. Reducing victims' risk of contracting a sexually transmitted disease, most victims do not experience a genital or anal injury during a sexual assault, and sexual dysfunction is not uncommon among male assailants. Among prepubertal victims, penetration, particularly of the anus or vagina, less frequently occurs, which reduces the likelihood that a prepubertal victim will develop a sexually transmitted disease.

It is impossible to estimate the true prevalence of sexually transmitted diseases after sexual victimization for several reasons. First, only a fraction of victims seek medical care after sexual victimization. In addition, even if an individual tests positive for a sexually transmitted disease, it is often impossible to state definitely that an infection was a result of the victimization, given that many victims are sexually active and most assailants are not tested for sexually transmitted diseases. Among victims who do seek medical care and who are tested for sexually transmitted diseases, most victims do not attend follow-up visits, which are necessary to ascertain whether the victim has developed a sexually transmitted disease as a result of the assault during the intervening weeks. Even among young children, for some sexually transmitted diseases, it is possible that the infection was acquired by other means, such as via vertical transmission (transmission from the mother to child).

The rates of positive sexually transmitted disease tests among individuals who have experienced sexual victimization have primarily been evaluated in female victims who report to a hospital or medical facility, generally in the immediate aftermath of a sexual victimization that involved oral, vaginal, or anal intercourse. Not surprisingly, given the many factors affecting the likelihood that a victim will develop a sexually transmitted disease

as well as differences in the sexually transmitted disease testing conducted, rates of sexually transmitted diseases found among victims have varied. Sexually transmitted disease rates among women and adolescents from developed countries who have experienced sexual victimization have ranged from 8% to 26%, with the most commonly diagnosed sexually transmitted diseases being gonorrhea, chlamydia, and trichomoniasis. In addition, it is estimated that in the United States, the risk of syphilis infection among female adolescent and adult victims is approximately 3%, and the risk of HIV infection is less than 1%. Sexually transmitted diseases have been documented in adolescent and adult male victims of sexual assault as well, but prevalence studies have not been conducted for this population. A few studies have examined sexually transmitted diseases among primarily female children and adolescents from developed countries suspected of having experienced sexual abuse. The rates of sexually transmitted diseases among prepubertal children suspected of experiencing sexual abuse have ranged from 1% to 3%, and among postpubertal adolescents the rates have ranged from 5% to 15%.

Treatment of Sexually Transmitted Diseases Among Victims

Given the risk that an adolescent or adult seeking medical care after a sexual victimization will test positive for a sexually transmitted disease as well as the low rates of follow-up care, it is advisable to offer all victims sexually transmitted disease testing and prophylaxis. This prophylaxis involves treatment with antibiotics and antimicrobials, and it targets gonorrhea, incubating syphilis, chlamydia, trichomoniasis, and gastrointestinal parasites. If an individual has not previously been vaccinated for hepatitis B, vaccination is also recommended (although this requires attendance at two follow-up visits). However, less than two thirds of emergency rooms report routinely screening for sexually transmitted diseases among victims, and 30% of victims seeking care at an emergency room were not offered sexually transmitted disease prophylaxis. Studies evaluating HIV prophylaxis after sexual assault have found low rates of completion of this regimen (generally around 10% to 15%), primarily

because of the side effects of the treatment. Thus, it has been recommended that HIV prophylaxis only be offered to those deemed to be at high risk of HIV transmission, such as those assaulted by HIV-positive assailants or injection drug users.

SEXUAL ORIENTATION AND VICTIMIZATION

A strong positive correlation exists between sexual orientation and the risk, frequency, and intensity of criminal victimization, especially violent offenses. Social scientists have determined that one's sexual orientation independently increases the odds of victimization through multivariate analysis using logistic regression. A range of constitutional (age, race, and gender), social (rurality, socioeconomic status, education, and marital status), and situational factors specific to the victimization event (activity such as work, school or shopping, alone or with others, and time of day) has been studied. When all factors are held constant, being gay, lesbian, or bisexual significantly increases the likelihood of being a victim of a violent crime. The extent of victimization is unknown because of underreporting of criminal events,

attributable to the exclusion of the gay and lesbian community, generally, as well as actual and perceived homophobia within law enforcement, the noncriminalization of some events, and the desire of a percentage of victims to keep their sexual orientation confidential. Accordingly, estimates that homosexuals are twice as likely as heterosexuals to be a victim of a violent offense such as assault, sexual assault, and robbery, are likely conservative. In addition to experiencing higher levels of violent victimization than others, gays, lesbians, and bisexuals also experience higher spousal abuse, which is also thought to be underreported.

The lifestyle and personal predictors of victimization, such as frequency of evening activities, urban residence, young age, and single marital status, are more common among gays, lesbians, and bisexuals. Sexual orientation is pronouncedly problematic in the context of prison rape, so much so that the U.S. Congress authorized the National Prison Rape Elimination Act and formed a Commission to effect reform. Although the prison rape act is a notable exception, the United States has not been as progressive as other advanced nations in addressing victimization of homosexuals as a special population.

Prevalence

Violent and Property Victimization

Only recently have public data sources begun to collect sexual orientation victimization statistics. For example, the General Social Survey did not include sexual orientation questions until 2004. The available data, however, suggest that gays, lesbians, and bisexuals exhibit consistently higher violent victimization rates than do heterosexuals, even when controlling for standard risk factors such as marital status, age, place of residence, and frequency of nighttime activities. Specifically, gays, lesbians, and bisexuals are more likely to be robbed or physically and/or sexually assaulted. Bisexuals experience heightened risks of victimization compared with their gay and lesbian counterparts.

Same-Sex Domestic Abuse

Domestic abuse in the gay, lesbian, and bisexual community is a dark figure (unreported crime), principally because most state codes do not account for

the possibility of same-sex domestic partners. As a consequence, domestic violence among same-sex partners may be uncoded and unrecorded. However, survey research suggests that same-sex domestic abuse is at least as prevalent in same-sex couples as heterosexual couples. Homosexual men, for example, are just as likely as homosexual women to experience domestic violence. Approximately one in five homosexual males will be involved in a physically abusive relationship at some point during their lives.

The extent of same-sex domestic abuse may be heightened because of ignorance, both public and personal. Because same-sex domestic abuse may not be deemed official domestic violence, police may be less likely to take protective action. Moreover, same-sex partners may be less educated about domestic violence and even unaware that they can be victims of domestic violence.

Bullying

The extent of homophobic bullying is unknown. Because public schools typically do not allow students to be questioned regarding sexual orientation, research correlating sexual orientation and bullying faces considerable obstacles. The few available estimates of homophobic bullying indicate that gays, lesbians, and homosexuals are far more likely to be bullied at school than their heterosexual counterparts. Victims of homosexual bullying are more likely to contemplate and attempt suicide. Unlike officially protected groups, such as racial and/or ethnic minorities, victims of homophobic bullying are unusually isolated because they often lack official protections. Many school jurisdictions fail to include specific prohibitions against homophobic bullying. Moreover, school personnel may be ignorant of the extent of homophobic bullying. As a consequence, bullied gays, lesbians, and bisexuals may have few outlets for help.

Prison Rape

Nearly one quarter of prison inmates are victims of rape. Same-sex sexual orientation is a risk factor in sexual predation in prison. Male rape victims are frequently branded as homosexual and subjected to even more predation. By being trapped in a coercive environment, prisoners are often threatened into feigning consent, which may lead to an underestimation of the true prevalence of prison rape.

Consequences

The consequences of sexual orientation-based crimes are multifaceted and manifest in immediate, temporary, and lasting forms. Although these outcomes are dichotomized below as physical and psychological, the effects of physical and mental health injuries are often interrelated (e.g., depression that results from injuries or health issues, such as considerable weight gain/loss and sleep deprivation stemming from anxiety). Victimization attributable to sexual orientation also renders additional social and quality-of-life consequences less pronounced than visible physical harm that, ostensibly, enhances the likelihood and/or duration of psychological effects. Gay and lesbian students, for example, may avoid abusive school settings to avoid homophobic bullying environments, thus risking designation as truant (i.e., delinquent) and, at the least, worsening their educational attainment.

Physical and Psychological Consequences

Victimization of gays, lesbians, and bisexuals involves more than the standard physical harms that accompany an assault. Psychological symptoms include fear, shock, depression, sleeping problems, anxiety, social withdrawal, anger management, helplessness, shame, and even suicide. Victims may exhibit posttraumatic stress disorder and experience lifelong social maladjustment.

Advocacy and Public Policy

Legislation

After celebrated cases such as Matthew Shepard, many states have implemented hate crime legislation, which officially recognizes sexual orientation as a protected category. Consequently, victimization based on sexual orientation subjects an offender to additional legal sanctions. Moreover, many school districts have endorsed special rules to protect students from being bullied based on sexual orientation.

In recognition of the prevalence of prison rape, the federal government has sought to curb prison rape via the Prison Rape Elimination Act of 2003 and the creation of the National Prison Rape Elimination Commission.

Nevertheless, because of ambivalence and/or hostility to gays, lesbians, and bisexuals, states and schools have been slow to protect sexual orientation victims. Legislators may fear appearing to be soft on gays or condoning an alternative lifestyle. Similarly, school administrators may fear condoning same-sex sexual orientations by providing official protection. Because of shame or embarrassment, gays, lesbians, and bisexuals may be afraid to identify themselves. As a result, America's formal system of social control systematically underserves sexual orientation victims.

Prevention and Intervention

Increased recognition of sexual orientation victimization has led to programming initiatives. The South Carolina Equality Coalition, for example, has provided sensitivity training to police and school resource officers aimed at educating police about the scope and nature of sexual orientation victimization. Many such activities are privately funded; public funding for such purposes is relatively rare.

Largely based on political reasons, the criminal justice and school systems remain resistant to intervention efforts. Because of formal constraints, for example, juveniles are not asked about their sexual orientation at school, effectively rendering problematic populations invisible. Moreover, public officials may be disinclined to use public funds to fund initiatives favoring gays, lesbians, and bisexuals.

SEXUAL VICTIMIZATION

Aside from rape, sexual victimization takes many forms, including experiences that involve physical and nonphysical contact. Examples of physical (non-rape) contact include unwanted sexual touching (fondling or groping), whereas types of nonphysical contact victimization include sexual harassment and stalking. All forms of sexual victimization entail experiences that are perceived as unwanted and harmful. Experiences of sexual victimization may or may not be defined as crimes, or as otherwise actionable events in different organizational settings. In general, the range of incidents defined as sexually victimizing has expanded over time, which reflects the increased cultural influence of feminism and the clinical influence of traumatology.

In 2006, according to the U.S. Department of Justice, the national rate of nonrape sexual assault victimization (including threats) among females age 12 and older was 0.5% per 1,000 (68,620 reported cases; rates for men were statistically negligible). Social scientists agree that rates reported to legal authorities grossly underestimate those reported in anonymous survey-based research. Such discrepancies in reported and unreported rates have been demonstrated in studies of college students, who are the most frequently studied population of sexual victims.

Risk Factors

The most important risk factor for heterosexual sexual victimization is gender: Women are significantly more likely to be victimized sexually than are men (less is known about sexual victimization among lesbian, gay, bisexual, and transgender

populations). Among women, those at highest risk are college aged. Among female college students, alcohol consumption and membership in sororities are established risk factors. Recent research shows that “hooking up” (single sexual encounters with no expectation of future relational commitment, which have largely replaced monogamous dating) is another significant risk factor for sexual victimization.

Although college and university life is usually perceived as safe, studies of both national samples and individual campuses consistently reveal sexual victimization rates (including rape and nonrape incidents) between 20% and 25% for women. Similar rates of serious disease outbreaks or other types of criminal victimization would likely lead to public outcry and concerted efforts at primary prevention, and so it is important to consider why sexual victimization has not led to such responses (although some recent efforts at primary prevention have shown promise). The most important factor in maintaining sexual victimization, both on campus and in the general population, is the continued hegemony of male socioeconomic power and heterosexism.

Consequences

Rape is rarely reported to legal or organizational authorities, and instances of nonrape sexual victimization are even less likely to be reported. Many such cases occur in private situations, in which perpetrator and victim are the only witnesses. Even in those cases in which victimization occurs in public (e.g., at a bar or a party), the perpetrator, victim, and potential witnesses are often sufficiently intoxicated that the reliability of their reports after the fact may be called into question. Indeed, many cases of sexual victimization that involve inebriation are never adjudicated because prosecutors cannot achieve convictions when the victim’s testimony will be challenged on this basis. Thus, sexual assault perpetrators may use alcohol and other sedating drugs on victims not only to facilitate the assault but also to hinder prosecution.

Psychological/Social

Reported or not, sexual victimization often causes significant, harmful psychological and

social consequences. Some preliminary evidence indicates that even seemingly innocuous incidents, such as unwanted sexual touching, may be related to subsyndromal levels of psychological symptoms (increasing attention is being paid to subsyndromal symptoms—symptoms the frequencies or intensities of which do not meet criteria for formal diagnosis but are nonetheless significantly disabling). Among the most frequent psychological consequences associated with sexual victimization are stress-related reactions that include acute stress disorder, posttraumatic stress disorder, and other commonly co-morbid conditions, such as anxiety (e.g., generalized anxiety disorder) and mood disorders (e.g., major depression). Difficulties with social and occupational adjustment are also likely to accompany sexual victimization.

Treatment and Prevention

Treatment for the psychological consequences of sexual victimization assumes that survivors avail themselves of therapy, but most survivors probably do not. In some cases that do receive clinical attention, cognitive-behavioral therapy (CBT) is the current treatment of choice. CBT is usually focused on repeated imaginal exposure to stressful/traumatic memories, in an effort to reduce the aversive emotional reactions associated with such memories. Although research clearly demonstrates the clinical efficacy of CBT, patients usually experience diminished symptoms, not cures. The lack of clinical cures underscores the importance of efforts at primary prevention. Some recent programs that use men to teach other men not to abuse women sexually have shown promise, but much more effort is needed to change individual perpetrators as well as the sexist social cultures that produce, encourage, and protect them. The rates of sexual victimization are unlikely to diminish until truly equitable relationships are established between women and men.

SHADOW OF SEXUAL ASSAULT HYPOTHESIS

The shadow of sexual assault hypothesis is a supposition used to explain women's fear of crime. Women's fear of crime is disproportionate compared with their actual rates of victimization. The shadow of sexual assault hypothesis asserts that the higher levels of fear among women may be because of their fear of rape or sexual assault. For women, any victimization may involve the risk of sexual assault, and women may then associate all types of victimization with sexual assault. Hence, a woman's fear of sexual assault influences her fear of all other offenses. This notion is important to the fields of victimology and crime prevention, as it provides some idea of how women view their potential for victimization and perhaps can provide some ideas on how to address the fear of victimization among women. Additionally, examining fear among women may also reveal information relating to precautions women take in order to prevent victimization. This entry describes the shadow of sexual assault hypothesis in more depth covering what led to the development of the hypothesis, research concerning the hypothesis,

and implications for addressing fear of crime among women.

Development

In relation to fear of victimization, females are generally more likely than males to fear victimization. Yet victimization rates for most crimes are typically lower among women than among men. The contradiction between actual victimization rates and levels of fear among women is somewhat of a paradox. To offer some explanation, a range of academic research on fear of crime has concentrated on female fear. One explored topic is the relationship between the actual rates of rape or sexual assault victimization of women compared with their fear of rape or sexual assault or other crimes. As female victimization rates of rape or sexual assault are significantly higher than victimization rates of men, this fear may perhaps be considered justified. In fact, the National Crime Victimization Survey consistently shows significantly higher rates of rape or sexual assault victimization among women than men. And the National Violence Against Women Survey found that lifetime rates of rape or sexual assault victimization were about 18% for women compared with only 3% for men. Women are also significantly more likely than males to report higher fear of sexual assault. And, more specifically, women are more likely to fear sexual assault by a stranger than an acquaintance, even though they are more likely to be sexually assaulted by an acquaintance. Furthermore, younger women express a greater fear of sexual assault than older women, and younger women are at an elevated risk of sexual assault, especially among college-aged women. Based on the inconsistent level of fear among women compared with their victimization in most crimes other than rape, some arguments regarding women's elevated levels of fear began to concentrate specifically on the fear of rape or sexual assault and its relation to other victimization fears.

Feminists argue that the threat of rape functions as a type of social control of women as it can affect their daily routines. Furthermore, they contend that women view their safety in terms of both sexual and physical ways, whereas men think of their safety as physical only. As a result of this

perception of safety and women's fear of victimization, women incorporate defensive tactics into their lives. In particular, women may incorporate self-protective measures specific to their fear of rape. Furthermore, it is possible that any victimization of women may involve the chance of sexual assault. Women may view the threat of victimization in this manner. Mark Warr considers these "perceptually contemporaneous offenses" or offenses that people may associate with another type of victimization. It is proposed that rape would qualify as one of these offenses to most, but in a particularly unique way, it is associated with the victimization of women. That is, women may associate some minor crimes, like burglary, with more serious crimes, like rape. Overall, the fear of rape may contribute to the fear of other offenses.

Based on this and various other feminist discussions of fear of victimization, Kenneth Ferraro developed the shadow of sexual assault hypothesis. This hypothesis asserts that sexual assault "shadows" other kinds of victimization among women. Women are more afraid of all types of crimes, but this hypothesis proposes that this fear is mainly based on their fear of sexual assault. For women, any victimization may also involve sexual assault, and this notion may lead to elevated fear for all other offenses. Overall, the shadow of sexual assault hypothesis contends that fear of rape or sexual assault affects other victimization fears.

Research

Since the development of the shadow of sexual assault hypothesis, research has been conducted to test its claim. If the shadow hypothesis is true, that is, fear of rape influences other victimization fears, then theoretically the fear of rape should correlate with other types of fear. To test this, both gender (if not a female only sample) and fear of rape are considered independent. In fact, strong correlations between women's fear of rape and other victimizations have been found. Specifically, a strong association exists between fear of rape and fear of victimizations that involve face-to-face contact. Furthermore, when one uses the fear of sexual assault as a predictor of nonsexual victimization, the explained variance in fear of other crimes significantly increases; in some cases, the effect of

gender actually disappears. If the gender effect remains significant with fear of rape taken into account, the relationship sometimes reverses; to be exact, women exhibit less fear than men. When controlling for the variable(s) used to measure fear of rape, this variable is generally shown to be the strongest predictor of all other types of fears. Interestingly, these effects emerge more so when predicting fear of personal crime. That is, the shadow effect seems stronger concerning fear of personal crimes, such as murder or physical assault. In addition to examining fear of nonsexual victimization, some have also analyzed women's fear of sexual assault, and the perceived risk of victimization is found to be the most important predictor. Researchers have also begun to examine the college population, as empirical evidence has shown that for women, the college years may be a period of elevated risk of rape and sexual assault; hence, the shadow of sexual assault hypothesis may work as an explanation of college women's fear of other crimes. Like other samples, college women are significantly more fearful of crime than college men, and the shadow hypothesis seems to also be supported among college samples. More recently, temporal differences have also been considered in the fear of crime research area comparing fear during the day versus fear during the night, and whether the shadow of sexual assault hypothesis predicts either fear better than the other. It turns out that fear of sexual assault is a significant predictor of fear of other crimes both during the day and night. Furthermore, research has questioned whether a distinction could be made between the fear of stranger-perpetrated versus acquaintance-perpetrated sexual assault, namely, whether one would predict other fears more accurately than the other. It has been determined the fear of stranger-perpetrated sexual assault is most related to women's other crime fears. In particular, the fear of stranger-perpetrated sexual assault is more highly associated with other stranger-perpetrated crimes. Generally, it is argued that empirical support exists for the shadow of sexual assault hypothesis both within the general population as well as among college students. Women may be more afraid of victimization, but this seems to be mainly because of their fear of rape or sexual assault. Overall, support for the shadow hypothesis shows that models of fear of

crime should include not only specific domain and temporal consideration but also fear of rape and sexual assault when considering fear of other offenses that involve face-to-face or personal contact. Future research is needed to continue to test the shadow of sexual assault hypothesis in other domains and to refine our understanding of the shadow of sexual assault hypothesis and the fear of crime among women.

Implications

The development and testing of the shadow of sexual assault hypothesis supports the notion that fear of rape and sexual assault must be addressed to affect the general fear of crime among women. With the knowledge from this hypothesis and the research surrounding it, it is hoped that effective social programs may be developed and existing programs with the aim to decrease fear of victimization be evaluated. Fear of victimization among women is prevalent, and knowledge about the subject as well as actual victimization risks may work to provide women with ways to keep themselves safe or at least make them feel safe. According to feminists, too much fear is incapacitating and limiting to women's activities, but arguably, some fear may promote using precautionary behaviors that may protect some women or keep them feeling safer. One particular population of concern is that of the college population, as they are at a heightened risk for sexual victimization; the research shows that fear among college women is significantly higher than that of college men, and some explanation can be provided from the shadow of sexual assault hypothesis. For instance, it is important that college administrators should focus their attention not only on actual victimization but also on the fear of victimization. Because gender proves to be the most significant predictor of fear of victimization, with females reporting significantly greater fear, perhaps programs could be specifically designed for college women. Because research has shown support for the shadow of sexual assault hypothesis, it seems fruitful that policies or programs should be developed to address college women's actual victimization risk and fear of victimization from both strangers and acquaintances, as well as the shadow of sexual assault. However, it is argued that simply educating women to use

certain behaviors or resources to reduce the chance of victimization may not empower them, and it may actually create more fear. Therefore, it is suggested that colleges develop programs to assist women in risk assessment by educating them about their level as well as sources of risk of crime. Overall, the shadow of sexual assault hypothesis remains an important concern when considering how to deal with fear of crime.

SHAKEN BABY SYNDROME

In the United States, shaken baby syndrome (SBS) is the leading cause of death among cases of child abuse. SBS results when an infant is shaken vigorously, causing the brain to shift back and forth. This motion causes the brain to hit the skull and results in intracranial injuries. SBS may also stem from an infant being thrown either onto a bed, against a wall, or other surface that causes blunt force trauma to the child's head. SBS usually occurs when the infant is grabbed around the torso and shaken, or by grabbing their limbs and swinging them. The shaking motion typically occurs for between 5 and 20 seconds and often results in quieting the baby—the most common intended effect. The perpetrator, however, usually does not realize that the infant has stopped crying not because he or she was soothed by the shaking motion, but because brain damage has occurred.

The shifting motion experienced by the brain in SBS is similar to what occurs during motor vehicle crashes resulting in whiplash. However, the type of damage that occurs from this type of movement can be more severe for infants than is typically found among other age groups and therefore can have more devastating effects. This is because infants' heads are disproportionately large compared with their bodies, and their neck muscles have not fully developed and are therefore not strong enough to support their heads.

Victims

Most victims are younger than 1 year of age, and the average victim is between 3 and 8 months old. However, it is not uncommon for children up to 4 years of age to be shaken. About 60% of victims are males. This may partly because of misconceptions that male babies should be treated differently from female infants. The higher prevalence among male infants may be attributable to gender stereotypes that male babies should

“man-up” and learn at an early age to not be emotional or cry. Or, caregivers may wrongly believe that male babies are stronger and can better withstand more physical handling than female babies.

Victims may be taken to the hospital or doctor for treatment after the incident. When asked by a medical staff member, many offenders will suggest that he or she was simply bouncing the baby on his or her knee, or that the infant fell off the couch. However, SBS will not result from these types of activities. The movement involved in SBS is so violent that these motions will not result in the types of damage encountered after an infant has been shaken. In some cases, the injuries will not be noticeable until years after the incident. If the injuries are identifiable and congruent with child abuse of any kind, such as SBS or another form of abuse, then physicians are required to report any individuals suspected of child abuse to child safety authorities. Any medical employee who fails to report child abuse can face legal and professional sanctions. Physicians may misdiagnose cases of SBS in infants manifesting milder injuries leading to an underestimation of the true prevalence of SBS. Children who do not have injuries congruent with child abuse are often diagnosed as having colic or a viral infection.

Consequences

Even one instance of shaking a baby can result in both immediate consequences and long-term outcomes that are often beyond repair. Each year, between 1,000 and 3,000 infants are diagnosed as having suffered from SBS, and one quarter to one third of these children die from the trauma. The shaking may rupture the blood vessels and nerves in the brain that can lead to bleeding. Bruising and swelling in the brain may also occur. Other possible injuries include fractures of the skull and bones (including the ribs if this is where the baby was grabbed), whiplash, spinal cord damage, swelling of the brain, neurological symptoms (e.g., seizures or lethargy), blood clots in the brain, and bruising on the body of the child where he or she was gripped by the offender. One telltale sign of SBS is hemorrhaging in the retinas of the infant's eyes. Ocular injuries and retinal hemorrhaging (i.e., blood spots on the eye) are one of the most prevalent injuries in cases of SBS and other abuse.

About one third of SBS victims can expect a sufficient recovery. However, all infants who suffer from SBS may experience behavioral problems over their life course. Sufferers of SBS may be impulsive, apathetic, and lack inhibition because of frontal lobe injuries. Other health-related consequences include blindness, hearing loss or deafness, seizures, and developmental delays, such as impaired speech, partial paralysis, cerebral palsy, learning disabilities, and attention problems. They may have problems with lethargy, decreased appetite, and difficulties reaching normal infant milestones. Furthermore, scores on IQ and memory tests may be below average and special education classes may be necessary when the child enters school.

Recovery from SBS is impeded because of the young nature of the victim. Infants' brains have had little time to learn and store information, and the trauma to their brains may impact their ability to acquire new knowledge and the need to compensate for their injury and any deficits is an added burden. Victims may need physical and/or occupational therapy to progress along standard developmental pathways, develop skills, and reach age-appropriate milestones.

Perpetrators

Offenders may shake a baby out of frustration when the infant is crying. They are often stressed and do not know how to handle and console a restless baby properly. Perpetrators of SBS are often parents or caregivers. Males, particularly young males in their early 20s, are the primary offenders. About 37% of all perpetrators are the biological fathers, and about 21% are boyfriends of the child's mother. Another estimate suggests that biological fathers and biological mothers' boyfriends are responsible for 65% to 90% of all cases of SBS. After fathers and mothers' boyfriends, babysitters are the most common perpetrators. Children's mothers are infrequently the source of SBS. Offenders are often detached emotionally from the infant or child. This is particularly the case in situations where the offender is the biological mother's boyfriend. It is much easier to inflict harm on someone to whom you are not emotionally attached.

A key risk factor for SBS is a lack of parental preparedness to care for the child—including inability to soothe a crying child, poor coping skills under stressful situations, alcohol and/or drug use or abuse, poor anger management, and feelings of being overwhelmed (perhaps because of more than one infant child in the home or multiple births). Additionally, being a young parent or caregiver increases the chances that an infant will be shaken. Children are also at increased risk if they are from a family that lives at or below the poverty level. Disadvantaged families may experience the added stressors of trying to support a family and may lack social support (e.g., relatives and friends) to deal successfully with the strain of caring for a child.

Another reason an individual may shake a baby might stem from personal experience as an abused child. Perpetrators who were abused as a child may not know appropriate ways to handle a crying infant and are at increased risk of shaking a child. Persons who were abused as children may mimic behaviors they encountered or witnessed growing up and may believe that they are parenting appropriately. Alternatively, perpetrators who were abused as children may seek to avenge their past and project their anger onto an innocent child. In either case, this perpetuates a cycle of violence.

Criminal Prosecution

If SBS is identified accurately, the offender may be criminally charged and stand trial in court. Perpetrators in cases where the victim dies as a result of SBS are likely to be charged with homicide. Depending on the intent of the perpetrator, he or she may be charged with first- or second-degree homicide, reckless homicide, or manslaughter. If a victim survives, the offender will be charged with a lesser crime, such as child neglect or endangerment. The penalty sought will also depend on the outcome of the incident. Graver outcomes (e.g., death) will garner more severe penalties (e.g., jail or prison).

To argue the case successfully, the prosecutor must educate the judge and jury about the causes and consequences of SBS. Medical personnel and law enforcement officers play a key role in providing accurate evidence to support the charge. Physicians and nurses can interpret medical tests performed on the victim and describe the consequences of

sustaining injuries from SBS. Law enforcement officials can assist by thoroughly investigating the case, interviewing all parties involved, and evaluating the evidence.

Secondary Victims

SBS directly affects the infant or child who was shaken, and it also affects the parents and caregivers who did not inflict the injuries. SBS victims who live may face a lifelong battle with various disabilities, and caregivers are left to deal with a momentary lapse in judgment on the part of themselves or someone they trusted to care for their child. Children with serious injuries will likely be disabled or have special needs. They may require continuous care or additional support to meet developmental milestones. Parenting a disabled child, particularly one with SBS, can lead to psychological and emotional problems. Possible psychological issues among caregivers include depression, grief, fear, betrayal, posttraumatic stress disorder, and denial. They may also suffer from guilt for putting the child in danger as well as for the resulting injuries and disablement of the child.

Prevention and Intervention

Shaken baby syndrome is completely preventable and early interventions have been successful. Parents and caregivers should be educated on the devastating effects of SBS and taught how to properly handle a crying infant. In lieu of shaking, many alternatives are available to quiet a crying baby. These include rocking a baby in a chair or infant swing, taking the infant for a ride in a stroller or car, providing a pacifier, and making sure basic needs (e.g., food, sleep, and diaper change) are met. For at-risk families or parents, at-home visits from nurses after release from the hospital can provide a means for teaching appropriate parenting skills. These types of programs have been successful for reducing child abuse and future consequences (e.g., delinquency and aggression) of child abuse. Babysitters and other child care professionals should also be educated on how to care for infants and children correctly. Anyone who is given the responsibility of caring for a dependent child should be taught how to do so appropriately.

Another important preventive factor is social support. Many perpetrators of SBS do not have sufficient resources or support to care for an infant, particularly one that may be fussy. Reaching out to family members and close friends for assistance in caring for the child can provide a necessary respite and allow the caretaker to get some rest and regain control of their emotions before reaching the point where shaking may occur. Sharing the responsibility of raising a child or simply taking a brief time away from a stressful situation can help prevent shaken baby syndrome. For caregivers who cannot depend on others for assistance, leaving a baby for 10 minutes in a safe environment such as a crib while stepping out of the room to regain control can prevent incidents of shaking, prevent injuries associated with shaking, and potentially save the child's life.

SITUATIONAL ACTION THEORY

The following three fundamental questions need to be addressed when developing an explanation of

acts of crime and devising effective crime prevention: (1) What is crime (what is it we attempt to explain and prevent)? (2) Why do people engage in acts of crime (what are the immediate processes which move a person to carry out an act of crime)? (3) What person and environmental factors interact in moving people to engage in acts of crime?

Situational action theory (SAT) is a recently developed theory that aims to explain moral action and crime. The theory builds on insights from various traditional criminological theories and research traditions as well as draws on social and behavioral science theory and research more generally. It sets out to overcome key common shortcomings in existing criminological theory, such as (1) the problem of the concept of crime (not being clear about what the theory aims to explain), (2) the problem of distinguishing causes and correlates (a poor understanding of causal mechanisms that often lead to a mixing up of markers and symptoms with causes), (3) the problem of integrating levels of explanation (a poor understanding of how person and environmental factors interact in causing acts of crime), and (4) the problem of explaining development and change (a poor understanding of the role of processes of development and change in crime causation).

Key Arguments

Situational action theory seeks to explain moral action and crime by explaining the key processes that lead to acts of crime (and transgressions of moral rules more generally), as well as the person and environmental factors which directly (and indirectly) influence those processes.

The key arguments of situational action theory are as follows:

1. Acts of crime are moral actions (actions guided by what is the right or wrong thing to do or not to do in a particular circumstance) and therefore need to be explained as such.
2. People engage in acts of crime because they (a) come to see such acts as a viable *action alternative* and (b) *choose* (habitually or deliberately) to carry them out.
3. The likelihood that a person will come to recognize an act of crime as an action alternative

and choose to carry out such an act ultimately depends on his or her morality (his or her action-relevant moral values and emotions) and its interplay with the moral context in which he or she develops and operates (its action-relevant moral rules and their enforcement).

4. To understand the role of broader social factors and their change (e.g., social integration and segregation) in promoting acts of crime, it is essential to focus on identifying how such factors influence the emergence of and change in (relevant aspects of) the moral contexts in which people develop (have their moral development) and act (express moral habits and make moral judgments).

Foundations of the Theory

The aim of SAT is to provide causal explanations that tell us *why* and *how* acts of crime occur. Situational action theory is based on a realist perspective. Two important assumptions of *realism* are (1) the world exists independent of us and our theorizing about it (e.g., in science we do not invent causes, we *discover* them), and (2) many important explanatory processes are unobservable, or partly unobservable (i.e., scientific knowledge is *not only* what is observable).

Situational action theory argues that crime is best analyzed as moral action. Situational action theory defines moral action as action guided by moral rules about what is right or wrong to do in a particular circumstance. It defines crimes as breaches of moral rules defined in law. Acts of crime are thus viewed as a special case of moral rule-breaking more generally. The advantage of this definition is its focus on what all kinds of crime, in all places, at all times, have in common, namely, (moral) rule breaking. What is to be explained by a theory of moral action is thus why people (follow and) breach moral rules, and what is to be explained specifically by a (sub-)theory of crime is why people breach moral rules defined in law.

Any action that is guided by rules of what it is right or wrong to do in a particular circumstance is a moral action. There is no difference in that respect between, for example, stealing a CD from a shop or blowing up people by the use of a roadside bomb. Both are examples of moral actions.

Hence, both kinds of actions can be explained within the same theoretical framework. What may differ in the explanation of different kinds of acts of crime is not the process (the perception-choice process) leading up to the action, but the content of the moral context (the action-relevant moral rules) and a person's morality (the action-relevant moral values and emotions), which drives the process and the broader social processes (the causes of the causes) that generate particular moral contexts (contents) in which people develop and act. Both in the case of shoplifting and roadside bombings, the actor has to perceive the particular action as a viable alternative and choose to carry out the act. However, the specific moral rules that guide whether an act of shoplifting is perceived as an action alternative will differ from those that guide whether an act of roadside bombing is perceived as an action alternative.

Situational action theory is based on explicit assumptions about human nature and its relation to social order. Most criminological theory does not have an explicit theory of action. Those that do have a theory of action generally allude to the importance of choice (as guided by self-interest and rationality) without further detailing its role in the explanation of crime. Situational action theory accepts that rationality and self-interest (at times) play a role in guiding human action, but it reasons that on a more fundamental level, humans are rule-guided actors. Human actions (including acts of crime), therefore, ultimately have to be explained as rule-guided action.

Most criminological theory focuses either on the role of the person or the environment in the explanation of crime. Situational action theory is developed to overcome the common (but unfruitful) divide between person and environmental explanations of moral action and crime. It achieves this by proposing a situational mechanism (a perception-choice process), which links the person and his or her environment to his or her actions. It postulates that all action (including acts of crime) is ultimately an outcome of (1) what action alternatives a person perceives and, in turn, (2) what choices he or she makes. In contrast to most choice-based theories, which focus on how people choose among predetermined alternatives, SAT stresses the importance of why people perceive certain action alternatives (and not others) in the first place. Perception of

action alternatives thus plays a more fundamental role in explaining action than the process of choice (which is secondary to perception). Importantly, a realist approach acknowledges that different people may view the same reality differently, but it insists that this fact does not imply subjectivism and can be rationally explained (e.g., is caused by individual differences in experiences and knowledge).

One of the most difficult problems in explaining human action is reconciling the role of deterministic and voluntaristic forces in the explanation of action. Situational action theory aims to integrate behavioristic (deterministic) and voluntaristic (free-will) approaches to the explanation of moral action and crime. It does so by recognizing that human actions (including law abidance and acts of crime) may be caused either by habit or rational deliberation. It argues that only in choice processes when people deliberate do they exercise free will and are subject to the influence of their ability to exercise self-control (internal control) or respond to deterrence cues (external controls). Whether a choice of action tends to be an outcome of deliberation or habit depends on the actor's familiarity with the circumstances in which he or she operates. Habits are created by repeated exposure to particular circumstances, which leads to action becoming automated, rather than deliberate, in these and similar circumstances.

Although acknowledging that motivation (desires and commitments) has a general directional influence on moral action, SAT states that the crucial factor in the explanation of moral action is the interplay between the morality of the person (values and emotions) and the moral context in which he or she operates. The outcome of this interaction will serve as a moral filter to determine whether a person will act on his or her desires or commitments. Many people are, for example, disadvantaged and frustrated for various reasons, without breaking moral rules to overcome or change conditions perceived to cause their disadvantage or frustration. Motivation (in terms of desires and commitments) is a necessary but not sufficient factor in the explanation of moral rule breaking (and crime).

The Causes of Acts of Crime

The causes of moral actions are factors that influence the moral perception of action alternatives

and influence the process of moral choice. Causes of crime are thus factors that influence a person to view an act of crime (a particular crime) as an action alternative and factors that influence a person's process of choice to carry out such an action alternative.

According to SAT, all moral actions are an outcome of the (causal) interaction between a person's propensity (to engage in the particular moral action) and his or her exposure to environmental inducements (to engage in the particular moral action):

$$\text{Propensity} \times \text{Exposure} = \text{Action}$$

The process that links the interplay of propensity and exposure to action is the "moral perception-moral choice process," as detailed earlier. This process can, depending on the familiarity of the circumstances, be predominantly habitual (expressing moral habits) or deliberative (expressing moral judgments) in nature.

Individuals will vary in their *propensity* to engage in a particular moral action depending on their moral rules and emotions. Moral emotions (shame and guilt) attached to violating a particular moral rule may be regarded as a measure of the strength with which a person holds a particular moral rule. For example, although many people may think it is wrong to steal something from another person, some may feel strongly about this whereas others may not. Those who feel less strongly about stealing from others may be regarded as having a higher propensity to engage in such action.

An individual's ability to exercise self-control (i.e., to act in accordance with his or her morality in the face of temptations and provocations) can also affect his or her crime propensity significantly. An individual's ability to exercise self-control is influenced both by relatively stable individual characteristics (executive capabilities) and momentary influences, such as high levels of stress and intoxication. However, the ability to exercise self-control is only important when an individual perceives crime (or moral rule-breaking) as an alternative, because self-control exerts its effects through the process of choice. When an individual deliberates over whether to commit an act of crime, his or her ability to exercise self-control influences the process of choice and plays a causal role in his or her decision to offend (or not offend).

It is important to bear in mind that propensities always need some environmental inducement to get activated. People do not act in a social vacuum. Individuals will vary in their *exposure* to moral contexts (external moral rules and their enforcement linked to particular circumstances). The extent to which moral rule following in a particular context is enforced (supervised and breaches sanctioned) may be regarded as the strength of the moral context.

If there is a high degree of correspondence between a person's morality and the moral context in which he or she operates, then it is likely that he or she will abide by the moral rules of the particular context. That is so because he or she will not recognize breaching the moral rules as a viable action alternative. If a discrepancy is found between a person's morality and the moral context in which he or she operates, then a particular moral action *deterrence* will be one important factor influencing whether he or she will act on a motivation to breach a moral rule (or commit an act of crime).

According to SAT, changes in a person's actions stems from changes in his or her propensity and/or changes in his or her exposure. This also implies that if one wants to change (or prevent) a person's moral actions, the aim should be to change his or her propensity (to engage in such acts) and/or his or her exposure (to environmental inducements for such acts), as follows:

$$\begin{aligned} &(\text{Change}) \text{ Propensity and/or } (\text{Change}) \\ &\text{Exposure} = (\text{Change}) \text{ Action} \end{aligned}$$

Changes in propensity and exposure are not unrelated in a developmental perspective. Changes in exposure may lead to changes in propensity (through socialization and habituation), whereas changes in propensity may lead to changes in exposure (through selection). The key developmental concept in SAT is moral education. People internalize moral rules (and emotions) through processes of learning, through others' responses to their actions, and through observation of others' actions and their consequences.

The Causes of the Causes

The role of broader social factors and individual development in crime causation may be regarded as a question of *the causes of the causes*. According

to SAT, factors that influence how particular moral contexts emerge and are sustained and factors that influence moral development (and the development of a person's ability to exercise self-control) are particularly interesting causes of the causes to address when analyzing moral action and crime.

Societies vary in their social integration (cohesion and trust) and moral integration (homogeneity of moral values held by the population and their correspondence to moral rules expressed by the larger society, e.g., in terms of laws). It is reasonable to assume that societies that have higher degrees of social and moral integration will have less moral rule breakings and crime because there will be less room for a discrepancy between individual and collective moral rules.

Changes in the broader social environment in which peoples' daily lives are embedded (e.g., political, economical, and social changes of relevance to moral actions) may instigate changes in the kinds of moral contexts present in a society and the processes of exposure of different groups of people to particular moral contexts. This, in turn, may (in the longer term) affect the moral education of the population or segments of the population, as well as (in the short term) the moral contexts in which people, or groups of people, act.

Key Questions for Research and Prevention

A research program built on and guided by the insights from SAT suggests that researchers should focus their analyses and research on addressing the following questions:

1. What kind of moral values and moral emotions support perceptions and choices relevant to peoples' engagement in acts of crime (and particular acts of crime)?
2. What aspects of the social and moral context (a) support the moral development of such values and emotions and (b) instigate their enactment?
3. How do social and moral contexts which promote the moral development of supportive moral values and emotions and the enacting of acts of crime emerge and how are they sustained?

The better researchers can answer these three questions, the stronger the knowledge base will

be on which they can develop effective crime-prevention strategies and interventions. According to SAT, the most effective ways to prevent crime are (in order of importance) the successful development of interventions as follows:

1. Make people not see crime as an action alternative.
2. Prevent the emergence of, and/or break existing, moral habits which promote acts of crime.
3. Influence the decision making of those who consider (deliberate) committing an act of crime.

The extent to which one succeeds in achieving the first goal is the extent to which the other two will be redundant.

SITUATIONAL CRIME PREVENTION

Situational crime prevention is the science of reducing opportunities for crime. It focuses on specific forms of crime or disorder and analyzes the opportunity structure giving rise to these problems—in particular, the immediate settings in which they occur. It then seeks to identify the changes in the design and management of these settings that will reduce crime with fewest economic and social costs. The changes are intended to discourage potential offenders by increasing the risks or difficulty of crime, making it less rewarding or excusable and reducing temptations or provocations.

Early situational prevention projects focused on ordinary crimes of burglary, car theft, vandalism, robbery, street prostitution, and violent assaults. More recently, situational prevention has been applied to a greater variety of crimes, in a greater variety of contexts, which include crime and misconduct in prisons, Internet frauds, organized crime, and terrorism.

Opportunity and Crime

Situational prevention is based on theories of environmental criminology, including routine activity theory, the rational choice perspective, and crime pattern theory. These theories share the following two assumptions that are important for situational prevention:

1. Opportunity is a cause of crime. Crime can only be explained as the result of the interaction between two broad causes: criminal motivation and opportunities for crime. Both must exist for a crime to occur. In fact, opportunity is an important cause of every form of crime, even a crime as important as homicide that is usually thought to be driven by strong motivation. This is shown by a comparison of homicide in the United States and in the United Kingdom. At present, the risk of being murdered in the United States is about 6 to 8 times greater than in the United Kingdom and in most other European countries. This is not because the United States is a more criminal country. In fact, recent research has found that rates of burglary and car theft are lesser in the United States than in the United Kingdom. Rather, the high U.S. murder rate is related to the widespread availability of guns, especially handguns, in America. In other words, the availability of guns is an important situational cause of homicide.

2. People are not compelled to commit crime by their backgrounds or personalities, but they choose to commit crimes because they judge these will bring them some benefit. The benefit is not always financial, but it might be excitement, sex, power, intoxication, revenge, recognition, loyalty, and love—indeed, anything that people want. Whether they choose to commit crime depends on their calculation of the chances of obtaining the reward and the risks of failure. Their choices may be made under emotional pressure or when intoxicated. They might also be split second, foolhardy, ill informed, or ill advised—but they are still choices.

These principles have important corollaries for situational prevention. First, criminally disposed individuals will commit more crimes if opportunities for crime increase. Second, generally law-abiding people can be drawn into committing

specific crimes if they regularly meet easy opportunities for these crimes. Finally, society unintentionally creates opportunities for crime by its physical and social arrangements. It produces “criminogenic” goods that facilitate crime, such as handguns or products that attract crime such as cars with weak door and ignition locks; credit cards with poor security; unprotected software; and high-value, easily stolen goods (“hot products”). It puts in place systems that inadvertently provide opportunities for crime, such as poorly regulated public drinking, inadequate checking of insurance claims, and banking procedures that facilitate money laundering. It designs and lays out places and buildings without thought to the crime opportunities they create, such as car parks without surveillance and shop displays that facilitate theft. It establishes poor management practices that result in crime, such as lack of staff on trains and buses, unsupervised football crowds, and disorderly, overcrowded pubs and clubs.

Reducing Opportunities for Crime

The following principles have been identified as crucial to the success of any situational prevention project:

- The project should deal with a very specific category of crime or disorder.
- It should seek to understand how the crime is committed.
- It should consider a variety of solutions.

Specific Categories of Crime

The situational determinants of any specific category of crime are different from those of another one, even one that seems similar. Each category may be committed for different motives, and by different offenders with different resources and skills. These points can be illustrated by research on residential burglary in one British city, which found that residential burglaries committed in the suburbs were different from those committed in the city center. City center burglaries were committed by offenders on foot, looking for cash and jewelry. Because the housing was mostly row housing, burglars could only get in through the front door or a front window. Suburban burglaries,

however, were committed by criminals who used cars and were looking for electronic goods, such as videocassette players and TVs. They were more likely to break in at the back of the house than the front. They needed cars to get to the suburbs and to transport the stolen goods. The cars had to be parked near to the house but not so close as to attract attention.

As these descriptions might suggest, the suggestions for preventing the two forms of residential burglaries were different. To prevent burglaries in the city center, it was suggested that security and surveillance at the front of houses should be improved. To prevent the suburban burglaries, it was recommended that security at the rear of houses should be improved and surveillance of parking places should be strengthened. It was also suggested that the police should crack down on fencing of stolen goods, particularly electronic items. Such a crackdown would have little effect on the inner city burglars who were primarily targeting cash and jewelry.

How the Crime Is Committed

These preventive suggestions depended on the knowledge of how the burglaries were committed and what goods were being sought. The researchers did not study why the burglars wanted to steal goods. It was enough to know that some are willing to break into other people's homes and steal things.

In trying to understand how a specific form of crime is done, the task should be examined from the offender's point of view. In doing so, interviews with offenders can be helpful, but an alternative is to "think thief." This strategy means putting oneself in the shoes of offenders and trying to think through the decisions that they must make to complete the crime.

This process reveals another important fact—committing a crime consists of a linked series of steps, each of which requires decisions to be made by the offenders. For example, burglars have to decide which houses to hit; how to get into them; which property to take; how to leave the house without being discovered; whether to sell or keep the property, and if to sell, how to do this, who to, what price to ask, and how to make sure that the goods will not be traced

back to them. Understanding in detail how a crime is committed helps in finding different ways to intervene.

It has often been argued that situational prevention cannot work because it does not attempt to understand or change motivation. It is true that a fuller understanding of motives can often assist situational prevention, but this is not always necessary. For example, an outbreak of random murders in the 1980s that resulted from people buying painkillers that had been laced with cyanide was eliminated by the introduction of tamper-proof packaging for all medicines and foods. The murderers were never arrested and their motivation remains obscure, but a straightforward situational measure eliminated future occurrences.

A Variety of Solutions

It is usually not difficult to identify a variety of solutions for any specific category of crime if it is analyzed in sufficient detail. To help identify possible solutions, researchers have classified the many different ways that exist to reduce crime opportunities. Situational prevention researchers have identified 25 opportunity-reducing techniques grouped under the following five main headings: (1) increase the effort, (2) increase the risks, (3) reduce the rewards, (4) remove excuses, and (5) reduce provocations.

The potential solutions identified in any project need to be assessed carefully for their cost and benefits. In all cases, the assessment must go beyond financial considerations and must include a variety of social and ethical costs, such as intrusiveness, inconvenience, unfairness, discrimination, and so on. Even if the assessment is informal, as it usually must be, this stage should never be skipped. Because opportunities can be reduced in many different ways, there is no necessity to adopt a particular solution if it is found unacceptable in certain respects.

Displacement

Many dozens of successful situational prevention studies have been reported since the concept was first described more than 25 years ago. In some cases, the reductions in crime achieved have been

dramatic. For example, U.S. cell phone companies largely wiped out cloning by the introduction of five new anticloning technologies; at its height in the mid-1990s, cloning had been costing the companies about \$800 million per year in fraudulent phone calls.

Despite these successes, some critics have argued that the reductions claimed are negated by displacement (e.g., the offenders shift their attention to other places, times, and targets; use different methods; or commit different crimes); that situational prevention results in escalation (i.e., offenders resort to more harmful methods to gain their ends); and that even if displacement does not occur immediately, the criminal population adapts in the long run to reduced opportunities by discovering new ways to commit crime.

The most persistent of these criticisms concerns displacement because it is often assumed that offenders are under a compulsion to commit crime. This may be true for some rare crimes—such as forms of arson—but it is not the case for most crimes. For example, it is highly unlikely that new security measures at a supermarket would lead local people, who had been accustomed to making small thefts in the course of their weekly shop, to shop at a more distant store where they could continue to shoplift.

In fact, the most recent review of displacement studies undertaken in 1994 by Rene Hesselting for the Dutch Ministry of Justice found no evidence of displacement in 22 of the 55 studies he examined; in the remaining 33 studies, he found some evidence of displacement, but in no studies was there as much crime displaced as prevented. If his review were repeated today, when many more studies of displacement have been reported, much the same would be found. For example, little displacement seems to have occurred to “subscriber” fraud, which is the second largest category of cell phone fraud, when cloning was eliminated by new technology. On the one hand, subscriber frauds involve the use of a false name and address to obtain cell phone service and would be difficult to reproduce on a wide scale. They would therefore not be attractive to organized groups. Cloned phones, on the other hand, were “mass produced” by offenders who had learned how to acquire hundreds of legitimate phone numbers and program them into stolen phones.

Diffusion of Benefits

“Diffusion of benefits” refers to the fact that situational prevention can often bring about reductions in crime beyond the immediate focus of the measures introduced. This general phenomenon is shown by the following examples:

- Closed-circuit television (CCTV) cameras installed to monitor parking at a university in England reduced car crime as much in a lot not covered by the cameras as in the three that were covered.
- When “red light” cameras were installed at some junctions in a large Scottish city, fewer drivers “ran the red” not only at these locations but also at other nearby traffic lights nearby.
- A regime of daily counting of valuable merchandise in the warehouse of a New Jersey discount electronic store substantially reduced thefts, not only of these items but also of other items not repeatedly counted.

The explanation for diffusion of benefits seems to be that potential offenders might know that new preventive measures have been introduced but overestimate their precise reach and scope. They might think the measures are more widespread than they really are and that the risks and effort involved in committing the crimes have been more increased than in fact is the case.

Anticipatory Benefits

Just as offenders often overestimate the reach of new preventive measures, they often seem to think that such measures have been introduced before they actually have been. As a result, crime drops before any measures have been introduced. This is what is meant by the “anticipatory benefits” of prevention. Anticipatory benefits have been found in about 40% of situational prevention projects, and it seems that publicity could be used to enhance these benefits.

Adaptation

Offender populations discover new crime vulnerabilities after preventive measures have been in place for a while. This is known as adaptation and is a longer term process than displacement, which

refers to the ways in which individual offenders seek to circumvent measures put in place to stop them.

One example of adaptation concerns the baggage and passenger screening measures introduced in the early 1970s to curb hijackings of airliners between the United States and Cuba. These measures quickly eliminated the hijackings and other countries soon followed suit, which meant that hijackings in those countries also declined. No real evidence of any displacement was found. For example, there was no increase in bombs placed on airliners. However, the authorities became increasingly lax over time, which allowed the 9/11 hijackers to find loopholes in the screening measures and seize the airliners. Their attack is a clear example of adaptation to preventive measures.

Blaming the Victim

It is increasingly understood that the government alone cannot protect people from crime and that people themselves have some responsibility for taking protective measures. Together with the fact that situational prevention includes measures that cause inconvenience or annoyance to ordinary members of the public, this has led to the claim that situational prevention “blames the victim.” This claim is incorrect, but at the same time it should be recognized that people often welcome advice that protects them from crime. For example, tourists often ask whether it is safe to use local taxis or to walk in the streets at night. It is also useful to know that British research has shown that putting cars in garages overnight considerably reduces the risks to car owners of falling victim to vehicle crime. For those with garages, they can then decide whether the reduced risk is worth the extra effort of putting the car away.

In cases where risks are taken in blatant disregard of the costs for others, those responsible are open to blame. A case in point would be shopkeepers who refuse to alter practices—such as displays to encourage impulse purchases—that they know increase the risks of theft. Despite this, they often expect the police to arrest any shoplifters.

Future Research

Situational prevention has been described as the fastest growing form of crime prevention in the

world. Much has been done in the past 20 years to reduce opportunities for crime through many different measures, which includes the widespread use of security guards, burglar alarms, CCTV surveillance, antifraud systems for credit cards, car immobilizers, better lighting, and improved building design. Despite this, situational prevention is rarely mentioned as a reason, perhaps an important reason, for the widespread decline of crime in most advanced western nations. Research is needed into the relationship between the combined effect of these and other situational controls and the crime drop.

SITUATIONAL CRIME PREVENTION, CRITIQUES OF

Situational crime prevention has been a controversial development and has struggled to gain acceptance within mainstream academic criminology. The concerns and approaches of situational prevention contrast in significant ways with those of traditional criminological theory. Where criminology generally seeks to understand offenders as well as the social and psychological forces that create them, situational prevention is concerned only with the immediate circumstances under which crime is performed. The situational approach promotes neither social reform nor offender rehabilitation, both of which are central themes elsewhere in criminology. Instead, situational theorists and researchers actively engage with police and other governmental agencies to help tackle immediate crime problems. For these reasons, situational prevention is often treated with skepticism and suspicion by other criminologists, and it is somewhat disparagingly classified as “administrative criminology.” Criticisms of situational crime prevention are of two broad sorts—those questioning the theoretical and conceptual adequacy of the approach and those attacking the ethical foundations and social outcomes situational interventions.

Theoretical and Conceptual Criticisms

Depending on the disciplinary assumptions made, most criminological theories explain criminal

behavior either as the response of offenders to macrolevel, sociocultural factors, such as social disadvantage and economic disparity, or as an expression of a criminal disposition created by each individual offender's biological makeup and life experiences. Situational analyses examine neither the sociological contexts of criminality nor the development of criminal dispositions, and theoretical criticisms of the approach center on these omissions.

The Situational Approach Is Sterile, Simplistic, and Atheoretical

It is claimed that the situational approach lacks the vigor, complexity, and sophistication of other criminological theories and amounts to little more than common sense. Situational analyses might explain where and when crimes occur but contribute little to our understanding of why crimes occur. Situational crime prevention, in turn, relies on mindless target hardening and is a simplistic response to a complex social problem.

In response to this criticism, it is argued that situational prevention is based on a fundamental tenet of modern psychology that all behavior arises from a person-situation interaction. Situations are not just places in which crimes occur; they play a causative role in initiating crime and shaping its course. Situational prevention is underpinned by rational choice theory, routine activity theory, crime pattern theory, and social and environmental psychology. Furthermore, target hardening is just 1 of 25 major techniques of situational prevention, and the selection of appropriate intervention requires a detailed analysis of the crime problem in question.

Situational Prevention Ignores the Root Causes of Crime

It may be conceded that situational prevention has a theory base, but those theories do not examine factors such as poverty, inequality, discrimination, poor parenting, and so on, which are the root causes of crime. By focusing on the performance of criminal behavior, situational prevention attacks the symptoms and not the underlying, systemic causes. It can at best provide a pragmatic, stop-gap solution to crime problems.

In reply, it is a fallacy that one must understand and change the historical causes of a behavior to

change that behavior. Random breath testing of motorists significantly reduces drunk-driving offenses independently of the psychosocial dynamics of alcohol abuse. Moreover, situations are one cause of behavior, and the distinction between root and nonroot causes is arbitrary. One might equally criticize other theories for ignoring situations. Indeed, a counterargument can be made that those causes that are nearest to the performance of behavior have the most powerful effect and are also the most amenable to intervention. It is difficult to make parents love their children more but relatively easy to make houses more difficult to burgle.

Situational Prevention Will Only Displace Crime

A related criticism is that situational prevention may succeed in displacing crime but will not prevent it. Because situational prevention does not address offenders' criminal dispositions, if thwarted in one criminal endeavor, offenders will simply move on to other crime opportunities. They may seek out alternative crime locations, offend at different times, change to different targets, use different tactics, and/or commit other sorts of crimes. In some cases, situational prevention will make matters worse by encouraging offenders to escalate their crime efforts.

There is a superficial logic to this criticism, but its validity depends on an overestimation of the role of criminal dispositions in crime and discounting the role played by opportunity and other immediate environmental factors. The flaw in this criticism can be observed by turning the question around. If everybody stopped taking any security precautions—did not lock their houses, left their keys in their cars, gave out their credit card personal identification numbers (PINs), walked in dangerous neighborhoods late at night, and so on—would crime increase? If the answer to this question is “yes,” then clearly taking routine precautions prevents rather than displaces crime. Empirically, it has been found that displacement often does not occur, and where it does, it is invariably less than the amount of crime prevented. In fact, the reverse effect has often been observed—that situational interventions targeting one location or crime can have preventive effects beyond the original target (referred to as diffusion of benefits).

Situational Approaches Are Not Appropriate for “Irrational” Crime

Some critics concede that situational prevention may be effective for prudent crimes—that is, offenses such as burglary where there is a clear monetary gain involved—but maintain that it is not applicable to crimes of passion (such as acts of expressive violence) or ones that involve strong drives and deviant impulses (such as sex offenses). These offenses are caused by emotional and psychological deficits of the offender and are beyond rational control via situational intervention.

It is true that early situational interventions were largely applied to acquisitive crimes such as burglary. However, situational factors have also been found to be important in a range of “pathological” behaviors, which include suicide, child sexual abuse, serial murder, and drug addiction. It has been shown that many so-called irrational crimes involve decision making by offenders that is sensitive to the perceived consequences of the contemplated action. Moreover, situational prevention is not limited to manipulating the costs and benefits of crime, but it takes into account situational factors that might provoke crime. Thus, expressive violence might be prevented by altering situational conditions—crowding, frustration, excessive noise, and so on—that elicit aggression.

Social and Ethical Criticisms

Along with a theoretical commitment to the social causes of crime, criminology generally embraces an ideological commitment to social justice issues. Because situational prevention does not espouse a social reform agenda and instead works hand-in-hand with government and law enforcement agencies, it is often cast as a politically conservative approach that promotes Orwellian solutions to crime problems.

Situational Prevention Uncritically Supports the Status Quo

Situation prevention was originally developed in the British Home Office in the 1970s, and in the eyes of critics, it has remained a tool that the authorities use to manage social problems and to protect the interests of the rich and powerful. It focuses on the crimes of the poor and disadvantaged (burglary, thefts, and the like) while ignoring

crimes of the affluent and crimes against women and minorities.

The situational prevention of crimes such as burglary may disproportionately target the poor and disadvantaged offenders, but these crimes also disproportionately involve poor and disadvantaged victims. Moreover, situational prevention is increasingly being applied against a wide variety of crimes, including computer fraud, assault, and rape. The pragmatic focus on prevention of crime rather than on harsh punishment of offenders differentiates the approach from the political agendas of most on the political “right.”

Access to Situational Prevention Will Become the Privilege of the Rich

An alternative scenario with similar outcomes is that governments will increasingly withdraw support from publicly funded law enforcement and adopt a user-pay policy. Only the rich will be able to afford the necessary security to protect their property. This will not only leave the poor unprotected, but will increase the threat that they will be victimized as perpetrators seek out alternative targets.

It is obviously true that the rich can afford better security than the poor, but the significance of this is overstated. The rich still need to move about in the world at large, and like everybody, they benefit from living in a secure and orderly society. Little evidence suggests that governments are withdrawing from law enforcement, and in fact, “law and order” has become a standard issue in most election campaigns. The charge of displacement has already been addressed.

Situational Prevention Blames the Victim

Because situational prevention techniques often rely on citizens taking precautions against their own victimization, it is accused of blaming the victim. Shifting responsibility to victims is not only morally indefensible, but also it is another example of governments abrogating their role in law enforcement.

The evils of victim blaming are the most evident in extreme and emotive examples, such as blaming rape victims for wearing provocative clothes. However, as noted earlier, citizens happily take many routine security precautions in their daily lives, and situational prevention can assist them

with advice on what measures are most effective. It is unrealistic to expect governments to take responsibility for all aspects of public safety. In some cases, it is wholly appropriate to blame the victim. For example, businesses, which through their irresponsible practices generate crime problems—like pubs that serve patrons to intoxication and then experience high levels of violence—should contribute to the prevention of these problems.

Situational Prevention Is Invasive and Oppressive

Situational prevention conjures images of Big Brother and insidious social control. Situational prevention advocates increased surveillance of citizens through the use of closed-circuit television (CCTV), identity checks, and the like, and such techniques are an invasion of privacy and restrict personal freedoms.

It is true that situational prevention may involve increased surveillance. However, in democratic societies, there are checks and balances that generally ensure that personal freedoms are not unduly curtailed. People are prepared to tolerate the costs of increased surveillance if there are obvious benefits that are delivered. For example, the inconvenience of airport screening procedures is generally endured patiently by passengers who are more concerned about the threat of terrorism. Likewise, most customers are happy for their banks to monitor their credit card usage if this helps detect unauthorized transactions.

Situational Prevention Will Create a Fortress Society

For many critics, the logical end point of situational crime prevention is the creation of a fearful and distrustful society divided by locks, bars, walls, guards, and other forms of obtrusive security. Communities will disintegrate as those citizens designated as undesirable are excluded from public spaces, whereas those with the financial means hide in gated communities.

As noted earlier, situational prevention involves more than target hardening. Many situational techniques actually involve “softening” the environment and bringing communities together. For example, housing estates which incorporate situational principles will typically have designed-in opportunities

for residents to interact with, and look out for, one another. Likewise, many situational measures—for example, improved street lighting—can reduce fear of crime. Situation prevention does not advocate the profiling of “undesirables,” arguing instead that security measures should be deployed on the basis that anyone might exploit crime opportunities. Although the number of gated communities is increasing, most are built in low-crime areas, and security levels are often minimal.

SMALL BUSINESSES, VICTIMIZATION AGAINST AND WITHIN

The small business sector is an increasingly important component to larger economies. Small business operations act as a jumping-off point for entrepreneurs in both mature and emerging economies. Despite their importance, small businesses have a high failure rate. One important component to small business financial stress, especially in communities that need such operators the most, is the costs associated with crime and its prevention.

As most small businesses have low levels of capitalization and small profit margins, a single crime incident can be the deciding factor in success or failure. This entry is organized to reflect the following definitional issues related to small business: the availability and relative quality of crime data in the small business sector, recent research into small business crime, and identified internal and external threats to small business along with suggested crime-prevention tactics.

How we define small business goes a long way in determining the trends and impacts of criminal victimization faced by this class of commercial operator. The U.S. Small Business Administration has a fairly liberal definition of a small business, with most commercial sector concerns being defined as small if they have fewer than 500 employees. Another complication in defining small business is the question of whether to examine company-level data or establishment-level data; many large commercial concerns are made up a multitude of smaller branch operators or franchises that have operational scales similar to small businesses.

Aside from these definitional concerns, little comprehensive data are available that examine business victimization, whether large or small. An early effort to assess the damaging effects of crime on small business was performed in 1969 by Albert Reiss and Howard Aldrich for the Small Business Administration. This study was national in scale and looked at the impacts of business crime by business size and geographic location of the operation. This study determined the total costs against all U.S. businesses in 1967–1968 to be \$3 billion (\$18 billion in 2007 dollars), with small businesses and urban areas being disproportionately impacted by the costs of crime.

Another effort to track business victimization comprehensively occurred during the 1970s when the Bureau of Justice Statistics, as part of the National Crime Victimization Survey, sampled businesses in more than 20 U.S. cities about their experience with burglary and robbery. This survey found that rates of crime against business were substantial.

Currently, much knowledge of small business victimization comes from smaller efforts focused on specific case cities or even smaller geographies, such as select business districts. Work in this area has also shown significant levels of small business victimization, especially compared with residential

communities. Examples of cases include the work of Bonnie Fisher and Johanna Looye, who found that small businesses in the Midwest region of the United States had substantial crime exposures, with the failure rate associated with crime and its attendant prevention costs also being large. Donald Kuratko and his colleagues, who collected data by way of a small business survey, found that small businesses that deal in cash transactions were more likely to suffer losses and more likely to institute substantial prevention methods.

Although these few cases tell us something about the nature and extent of small business victimization, research on business crime has lagged for several reasons. The first is that many businesses do not wish to share their victimization experiences with researchers or the outside world. This is partly because of trends related to repeat victimization; that is, they do not wish to advertise their vulnerability to a larger audience. From a methodological standpoint, businesses are less likely to take the time to fill out a survey or respond to a phone enquiry because of productivity concerns.

Even if we do not have a complete handle on the problem of small business victimization because of a lack of good data, the crime risks faced by small business concerns are many. In general terms, the costs associated with small business victimization include costs to replace lost merchandise, costs associated with security measures and insurance, and personnel costs related to employee turnover. Each of these costs either result in a loss of profit for the operator or increased prices to consumers (or both).

The U.S. Small Business Administration has developed a compendium of crime issues facing small business. These problems include external crime threats such as robbery, burglary, shoplifting, and theft; check, credit card, and Internet fraud; and vandalism. In addition to economic loss for the establishments, both the owners and staff of small business concerns face threats of violent, personal crime, as well as property crime threats to their personal property and vehicles.

Internally, businesses are vexed by additional threats relating to embezzlement and employee theft, theft of trade secrets, business reputation losses, and interpersonal violence. Measures taken to curtail internal losses related to crime include employment applicant screening procedures, which

may involve performing a formal background check on the potential employee. A second internal issue is that of audit controls; this process establishes a clear financial control system. Such a system creates a chain of responsibility and is especially useful in curtailing embezzlement or other inside financial frauds.

Whatever the employment sector—but especially among retail and service sectors that are dominated by young and inexperienced workers—the establishment of management systems viewed by workers as fair and equitable is important in promoting honesty and establishing positive workplace norms. Management systems that express lines of accountability among employees and are clear on employment expectations, while providing the necessary tools for employees to meet these objectives, act as a line of defense against employee dishonesty.

SOCIAL CONTROL AND SELF-CONTROL THEORY

Victimization has many serious consequences for public health and safety. Indeed, experiences of

victimization—from extreme forms of personal victimization such as sexual assault and intimate partner violence to lower level, yet still significant forms of property victimization—touch many households and can have devastating consequences for families and communities.

It is important to understand patterns of victimization as well as consider how theories, in particular criminological theories, can help account for the causes and consequences of victimization. Increasingly, research illustrates the use and relevance of criminological theories for understanding victimization. Theories that involve learning processes and cultural experiences, as well as routine activities/lifestyle characteristics, all seem relevant for understanding certain forms of victimization. However, it has been increasingly recognized, especially based on more recent research, that control theories provide credible and useful explanations for understanding victimization.

This entry describes the unique features of control theories and applies them toward understanding victimization. In particular, this entry describes two prominent control theories—Travis Hirschi's social control and Michael Gottfredson and Travis Hirschi's low self-control theory—and explains how these theories account for forms of victimization. The entry concludes by examining strategies for preventing victimization based on the principles of these particular control theories.

Control Theories: Evolution and Key Dimensions

Control theories enjoy a prominent place among the landscape of criminological theories. Indeed, dating back to the early work of French sociologist Emile Durkheim in the early 20th century, control theories have emerged since the turn of the 20th century to provide explanations that account for variations in rates of crime across neighborhoods as well as explanations for why individuals become involved in crime and deviance. It is only recently that control theories have been employed to account for victimization.

According to Hirschi's social control or social bonding theory, deviance occurs because of an absence of social control. Under this theory, individuals are naturally antisocial and hedonistic. What needs to be accounted for and understood is

why people conform. According to the theory, people conform because of the strength of their social bond or bond to society. The social bond is composed of four subcomponents, which include *attachments*, or affectional ties to parents, family members, and peers; *commitment* to prosocial courses of action and pursuits; *beliefs* in the moral validity of the law; and *involvement* or spending time in prosocial activities. A strong social bond is expected to insulate individuals from their innate tendencies to be self-interested and deviant. Taken together, Hirschi's social bonding theory represents a plausible explanation for why crime and delinquency occur.

Given that social control theory asserts that deficient socialization processes are expected to free individuals up to act on their antisocial tendencies, it is plausible to expect that such a process could also free individuals up to experience victimization. Many individuals who offend also experience high levels of victimization. In general, research finds a strong linkage between the characteristics of offenders and the characteristics of victims. What many theories have attempted to ascertain is the precise relationships between victimization experiences and offending. Whereas Hirschi's theory of social control would suggest that persons weakly bonded to society would inevitably put themselves at risk for victimization because of their antisocial orientations and their lack of integration to prosocial institutional settings, other theories assert that victimization gives rise to offending behavior through processes of strain, as individuals are pushed toward delinquent coping based on their victimization experiences. By contrast, routine activity or lifestyle theories assert that offending behavior and lifestyles could easily give rise to victimization experiences. Some social cultural theories would also expect a similar relationship. However, an equally plausible interpretation is that the conditions that lead toward offending behavior also lead toward victimization experiences; this interpretation is put forward by Hirschi as well as by Gottfredson and Hirschi in their book *A General Theory of Crime*. This book provides a comprehensive statement about the nature of low self-control and why it reflects a useful way for understanding crime and related outcomes, such as victimization (e.g., car accidents, drug use, and bad marriages). Their book reflects

a clear extension and elaboration of Hirschi's earlier theory of social control theory.

Theory of Low Self-Control

Gottfredson and Hirschi's theory of low self-control provides a comprehensive explanation of criminal and analogous behaviors including victimization. Although the primary focus of the theory has been on explaining offending behavior, the theory also applies to a range of outcomes, which include victimization. The authors have acknowledged the similarities between victims and offenders, wherein they both share individual and social factors, and a strong relationship exists between self-reports of victimization and offending.

According to the theory, individuals are naturally hedonistic and self-interested. Persons lacking in self-control tend to have an inability to restrain themselves and are at risk of succumbing to temptations that maximize their pleasure. Individuals with low self-control tend to act in the moment and do not often consider the longer term consequences of their actions. There are many aspects or dimensions of low self-control. For example, persons with low self-control tend to be risk takers (as opposed to cautious), exhibit a preference for physical as opposed to mental tasks, are self-centered, have concrete here and now orientations (as opposed to a having a future orientation), have angry temperaments, have a low frustration tolerance, and tend to lack diligence (i.e., lazy). According to the theory, these characteristics or aspects of self-control tend to reflect a "unidimensional latent trait."

The causes of low self-control, according to the theory, rest in parenting failures or deficits. A lack of effective and consistent parenting skills and behaviors provides the context for early socialization processes that are problematic and incomplete. In particular, parents who provide lax, inconsistent, or highly erratic discipline, coupled with poor or inadequate supervision, are providing a rich environment for their children to fail in developing effective levels of self-control. In effect, the absence of such effective parental management strategies, over time, ensures that children do not effectively appreciate limits and boundaries and ultimately have their antisocial dispositions reinforced. In effect, such children fail to develop adequate levels of restraint or self-control, which

allows them to act on their inner most hedonistic tendencies and needs. Criminal behavior occurs, according to the theory, because individuals lacking in self-control, coupled with opportunities to act on their lack of constraint, offend in a particular situational context.

Links Between Control and Victimization

It has only been in more recent years that Gottfredson and Hirschi's theory has shifted focus beyond offending behavior, to consider other forms of analogous behaviors such as victimization. According to Christopher Schreck, individuals who have low self-control are at risk for victimization for various different reasons involving distinct processes. First, individuals who have low self-control tend also to be impulsive and perhaps do not recognize the impact of their behavior on others; therefore, these persons may not recognize their own victimization risks. Moreover, individuals with low self-control are likely to lack diligence and have a concrete, short-sighted time orientation; thus, they may not recognize particular risks for their own personal victimization or take proactive measures to minimize their own risks. Third, individuals with low self-control may also have dispositions toward risk taking and thrill seeking, which may increase their likelihood of having accidents and/or being victimized.

Individuals with low self-control tend also to have physical orientations as opposed to more cognitive orientations. Such individuals may not cognitively consider and weigh up the risks of a particular situation that may increase their risk for victimization. Such individuals are also more likely to engage in physical violence, including fist fights and assaults, which may increase their risk for victimization.

According to Schreck, individuals with low self-control tend to be highly self-centered in their orientations and as such may not have strong levels of friendship networks and social support networks; these relationships tend to minimize their victimization risks. Individuals with low self-control also are expected to have a low frustration tolerance (i.e., short fuses), and it is perhaps not surprising that they are often easily angered. In that context, it is expected that individuals with low self-control would be more violent as both perpetrators and victims.

As mentioned above, individuals with low self-control tend also to be thrill seekers and seek excitement without considering all the consequences of their actions. They tend not to take the precautions required against personal victimization, and their impulsive decision making places them in particular situations that can increase their risk for victimization. Some of these processes may also involve neighborhood-level influences, as persons with low self-control tend to be concentrated in areas with a high level of poverty and economic disadvantage. In such areas, there is often an overrepresentation of lax and/or poor parental management skills and ample opportunities to engage in crime and experience victimization.

Current Research Findings

Several studies have examined control theories in relation to offending behavior, but only a few have examined relationships between control and victimization. However, studies exploring the unique relationship between self-control and victimization have only emerged since the late 1990s. For example, based on a study of college students, Schreck found that levels of self-control were statistically associated with criminal victimization. Erik Stewart, Kirk Elifson, and Claire Sterk examined violent victimization among African American female offenders and found support for the relationship, thereby suggesting that links between low self-control and violent victimization, can be observed among an at-risk sample of minority females.

Alex Piquero and his colleagues examined whether self-control relates to both violent offending and homicide victimization. Using longitudinal data on released offenders in California, the authors found that, consistent with Gottfredson and Hirschi's theory, low self-control was significantly related to violent offending and certain forms of homicide victimization.

Schreck, Stewart, and Fisher provided a comprehensive examination of the role of self-control in understanding repeat victimization. Their findings, which are based on an analysis of three waves of data from a large multi-city data set, found that low self-control preceded victimization experiences and that victimization was persistent over time, more than other influences. While being careful to assert that many victims do not fit into

this pathway, the authors did make the point that at least for some forms of victimization, "those who have low self-control facilitate, provoke, or precipitate their own victimization" (p. 337).

In an interesting study, Stephen Baron and his colleagues examined the influence of low self-control on violence and victimization among 140 at-risk street (i.e., homeless) youths in Canada. The study was significant because it emphasized to a greater extent the situational factors in close proximity to criminal events, in addition to dimensions of self-control. Moreover, the authors disaggregated self-control into the six component parts mentioned in the theory. The authors actually found that the risk-taking component of self-control was the only clearly related dimension that was significantly related to victimization. These findings are significant because they suggest that perhaps only certain aspects of low self-control are especially important in understanding why some forms of victimization occur.

Finally, in a 2008 study, Schreck, Stewart, and Wayne Osgood sought to separate and understand the role difference between offending and victimization. They found a great deal of overlap between many predictors of offending and victimization drawn from available theories, including Hirschi's theory of social control. However, in terms of role differences, they found that youth who get drunk frequently had a stronger tendency toward perpetrating violence than experiencing victimization, and offenders who were older tended toward more victimization experiences as opposed to violent offending behavior, in part because they may be aging out of offending behavior but still are exposed to risks for victimization in their environment.

In summary, although only a limited number of research studies have examined victimization from the perspective of control theories, some of the existing research suggests that control, including aspects of self-control, is related to victimization. These findings suggest that addressing aspects of control and self-control could help prevent victimization experiences.

Preventing Victimization: Strategies Based on Control Theories

Control theories are useful in informing efforts at preventing various forms of victimization. In

general, increases in informal social control or social bonding would reduce individual involvement in delinquency as well as victimization. Efforts at strengthening social bonding and improving levels of self-control with a view toward preventing victimization could occur through a series of programs and activities. For example, programs that foster more effective relationships between parents and children are worthwhile investments and would go some way toward fostering more effective ties and parental attachments. Moreover, efforts at improving parental management skills would foster more prosocial development of children and facilitate stronger affectional ties as well as higher degrees of constraint and self-control among youth. Parent training programs, such as those developed by Gerald Patterson in Oregon, Matthew Saunders in Australia, and David Fergusson in New Zealand, all show positive effects and illustrate worthwhile and cost-effective investments for raising self-control and reducing levels of victimization and related outcomes.

The school, as an institution of social control, provides a unique opportunity to embed young people into prosocial environments and pathways that reduce their opportunities for victimization. Programs aimed at fostering greater school commitment and performance, promoting prosocial beliefs, encouraging engagement with prosocial others and related extra curricular activities can provide worthwhile prevention investments. Kids who remain in school, as opposed to dropping out, tend to have better long-term outcomes. Moreover, programs aimed at reducing school bullying are worthwhile for preventing school-based forms of victimization.

In summary, the role of social control and self-control is important in efforts to prevent various forms of victimization. Programs have operated at either the familial or the school setting, and in general, efforts that foster higher levels of constraint in young children as well as provide further layers of social support, prosocial beliefs and awareness, and commitment to prosocial activities are significant in reducing victimization.

Conclusion

Control theories have a long history in criminology and have experienced resurgence since the

early 1990s. Although originally developed to explain crime and delinquency, more recent control theories can be employed to provide a useful explanation for victimization. Under this theory, victimization becomes another outcome for which individuals with low levels of self-control come to experience. Individuals with low self-control tend to be impulsive, have a physical as opposed to a cognitive orientation, are more likely to be self-centered, lack empathy, have angry temperaments, and have a thrill-seeking orientation. Consequently, they are often enmeshed in risky social situations where victimization is likely to occur, and they may not easily recognize their victimization risks. Moreover, the individual with low self-control is also quick to resort to violence, given their angry temperaments, thereby facilitating more risks for victimization. Such persons tend not to recognize their own personal victimization risks and are not committed toward taking proactive steps to minimize victimization outcomes.

Deficits in self-control are caused by ineffective parenting practices during early childhood, and it is expected that individuals with the lowest levels of self-control in childhood will also tend to be found in the lowest self-control group in adulthood, relative to other similarly aged individuals. The theory expects also that persons with established levels of low self-control are also at risk for persistent victimization risks given that they do not typically respond with a rational decision-making calculus to avoid future victimization experiences. Thus, efforts at minimizing victimization need to focus on the early years, to ensure that individuals are socialized to develop more constraints and healthy levels of self-control.

SOCIAL DISORDER

See Incivilities/Social Disorder

SON OF SAM LAWS

The victims of crimes forever bear the scars of the crimes that are committed against them. When the immediate victims are dead, the scars are born by the loved ones they leave behind. What makes this

situation even worse is when the killer or other perpetrator of the crime reaps a financial benefit from the crime by selling his or her story and becoming a celebrity. Although there is little that can be done to stop the media sensationalism of a crime, the law has tried to prevent those criminals from making money through telling their stories in books, television shows, and movies, unless the money is used in compensating the victim or the victim's families for their loss.

The Son of Sam laws, as they have come to be known, are the result of a \$75,000 book deal that resulted after David Berkowitz, the killer of innocent people, sold his story to the media. In 1976 and 1977, Berkowitz spread fear among New Yorkers by random attacks with a .44 caliber pistol that resulted in the deaths of six people and numerous injuries to others. People were afraid to walk the streets or sit in their cars, fearing that they would be the next random target of the killer. On the street near the shootings of Alexander Esau and Valentina Suriani in April 1977, the police found a letter addressed to Police Captain Joseph Borelli. The letter identified the killer as the "Son of Sam." In the letter, Berkowitz went on to talk about being programmed to kill and how he had been abused. In May 1977, Jimmy Breslin, who is a columnist for the *New York Daily News*, also received a letter. This letter included considerable psychotic ranting by Berkowitz, who signed it as the "Son of Sam." The police were eventually able to track down Berkowitz through a traffic citation he received in the vicinity of one of the crimes. As the story played out, Berkowitz stated that "Sam" was actually a former neighbor whose dog told him to commit the murders.

When New Yorkers heard about a proposed book deal, many were outraged by the attempt of a serial killer, Berkowitz, to profit from his crimes. This led the legislature to pass New York Executive Law Section 632-a (McKinney, 1982) that ultimately became known as the first Son of Sam law. More than 40 other states and the federal government passed similar legislation. The original law was written to prevent any convicted perpetrator from profiting from the sale of the story of his or her crime. Any proceeds were to be placed in a fund, to compensate the victims of the crime; but the Son of Sam victims would not receive any benefit from the original law. Berkowitz was never

tried and convicted of the crimes; he was declared incompetent to stand trial. However, "Berkowitz voluntarily paid his share of the royalties from the book *Son of Sam*, published in 1981, to the victims or their estates" (*Simon & Schuster Inc. v. Members of the New York State Crime Victims Board, et al.*, 502 U.S. 105, 111 [1991]).

The U.S. Supreme Court declared the New York Son of Sam law as unconstitutional, in that it was overly broad and impeded the First Amendment rights of the authors. In it *Simon & Schuster Inc. v. Members of the New York State Crime Victims Board, et al.*, 502 U.S. 105, 106 (1991), the court stated,

The New York law is not narrowly tailored to achieve the State's objective of compensating victims from the profits of crime. The law is significantly overinclusive, since it applies to works on *any* subject provided that they express the author's thoughts or recollections about his crime, however tangentially or incidentally, and since its broad definition of "person convicted of a crime" enables the Board to escrow the income of an author who admits in his work to having committed a crime, whether or not he was ever actually accused or convicted.

The *Simon & Schuster* case dealt with a book deal between Henry Hill, a writer, and his publisher. Hill was a convicted criminal and member of the Mafia who documented his exploits in the book *Wise Guy*, which was later the basis of the movie *Goodfellas*.

This ruling does not affect the ability of crime victims to seek restitution from those who commit the crimes through the filing of a civil or tort action, or a state victim's compensation fund claim. In cases where the victim is killed, the specific tort filed is called a wrongful death action. Most perpetrators of these crimes are not wealthy and cannot provide any financial compensation. By attaching any money received from selling their story, those victims would have an opportunity to recover something.

Where the crime involves a federal offense, Title 18 United States Code Section 3681 (2003) was passed to permit the prosecutor, after the defendant's conviction, to request the court to issue an "order of restitution under this title" requiring the "defendant to forfeit all or any part of proceeds

received or to be received by that defendant, or a transferee of that defendant, from a contract relating to a depiction of such crime in a movie, book, newspaper, magazine, radio or television production, or live entertainment of any kind, or an expression of that defendant's thoughts, opinions, or emotions regarding such crime."

Numerous other Son of Sam laws have been written, struck down, and rewritten. The rights of the people under the constitution have been preserved, as well as the rights of the victims to be compensated for the crimes that have been committed against them.

SPORTS VIOLENCE

A relationship exists between violence and sports. The relationship takes one of the following four forms: the violence of athletes while engaged in sports, the violence of athletes outside of competition, the violence of spectators proximate to a sporting event, and the violence of sports consumers. Explanations for these relationships include the following three broad mechanisms: learning or socialization, particularly traditional masculinity, and the physical arousal of sports participation explain the violence of athletes on and off the field and the violence of sports consumers. Violence between spectators tends to be explained

by the in-group/out-group processes between team supporters.

According to Sara Fields and her colleagues, sports violence is often typed as hazing, brawling, and foul play. Although these actions do seem to represent different activities and thus different types of violence, this typology ignores the interconnectedness between these activities. The correlations and their explanations noted above also suggest a high degree of interconnectedness.

Violence by Athletes on the Field

Violence by athletes on the field is required in many sports. In some sports—boxing, “ultimate” or “mixed-martial arts” fighting, and wrestling—the violence is the means and the goal of the athletic competition. For some sports—the various forms of football and stick games—violence is a means but not the goal of the competition. Still, other sports have rules limiting contact—basketball, water polo, baseball—but nonetheless can be extremely physical in nature. Finally, many sports have no physical contact whatsoever, although the act of competition itself can be viewed as a form of aggression. The intensity of the violence in each sport varies also by the local sporting culture. Coaches and supporters can teach and encourage a team or individual to enact higher levels of violence. The variation between sports and across locations is based on learning or socialization. Another variation is the level at which the sport is being played, with lower levels often, but not always, less violent than higher forms. This variation seems to be related to the arousal effects of high-stakes competition when compared with the lower arousal effects of recreational games.

Violence by Athletes off the Field

Violence by athletes outside of competition is the most researched of the four relationships. The arousal threshold of athletes and self-selection of violence-prone individuals into sports were once the most common explanations for this type of violence, but recently the emphasis has shifted to the ways in which sports inculcate the meanings and behaviors of traditional masculinity that includes physical domination and the use of violence to achieve an end. Derek Kraeger found that

male athletes, particularly those who engaged in sports where violence is part of the game, were more likely than nonathletes and athletes in less violent sports to engage in “serious fighting.” The effect was even stronger when the individual’s peers also played higher violence sports, which suggests a socialization effect. Gordon Forbes and his colleagues found levels of “dating aggression,” “sexual coercion,” and attitudes supporting aggression toward women were higher in males who engaged in more violent high-school sports. The sexist attitudes, expressions of hostility toward women, acceptance of rape myths, and low tolerance for homosexuality again suggest the effect of socialization. Inger Endresen and Dan Olweus found that young participants in “power sports” (weight lifting, boxing, wrestling, and martial arts) were more likely to exhibit antisocial behavior and violence. Collecting data for 2 years, the authors also demonstrated that the outcomes were not related to a selection effect where kids prone to violence select violent sports, but rather the data indicate that participation in the sports produced more aggression.

Spectator Violence

With the exception of post-game celebrations that have produced property damage, violence in and around stadiums by spectators has generally not been an American phenomenon. Fights between individual spectators are rare but do occur, and few deaths have occurred as a result. Outside the United States, violence between the supporters of opposing teams is such a concern that Interpol keeps a database of “hooligans” they track and sometimes prevent from attending games. Stefan de Vreese examined data from 9 years of Belgian soccer and found that all the violence (4,240 incidents) occurred between opposing groups of “hard-core” supporters where the “other side” is viewed as weaker and inferior and thus deserving of an attack. Examining news reports on English soccer violence, Eric Dunning argues that the violence is the result of a combination of masculinity and territorial struggles. Protecting one’s home turf from the other side’s supporters is a source of status. This mechanism, Dunning argues, explains the observed violence between national team supporters, regional rivalries, and the conflicts between the subnationalist teams in Spain.

Sports Consumption and Violence

Violence by sports consumers is a relationship with much research but little resolution. Some early studies in psychology found that people who view violence became more violent, which is an arousal effect (see the famous punching bag experiments with children in the 1970s). This mechanism was also applied to those who consume violent sports. After an initial flurry of research on this topic, the pace has slackened since 2000. Carolyn Sachs and Lawrence Chu recently found a strong relationship between professional football viewing and domestic violence. Domestic violence declined in the football offseason but increased as the football season got under way and peaked during the play-offs and Super Bowl.

Another way of examining this relationship is to study the consumption habits of a particular culture. The United States is widely viewed as a “violent” nation and ranks high in homicides and other forms of violence. J. C. H. Jones and his colleagues examined the effects of attending hockey games on fan attendance and found a positive relationship between the amount of violence on the ice and the game attendance. The more violent the game, the better attended it was, although this was true for the American audiences but not the Canadian audiences. Michael Atkinson examined the phenomena of professional wrestling and its appeal to excitement through violence. The study does not connect consuming violence to violent behavior; instead, it examines the symbolic meaning of the demand for violent entertainment, the consumption of violence, and what this says about the culture as a whole.

STALKERS, TYPES OF

The early stages of understanding behavioral phenomena often begin with attempts to identify types of individuals engaging in such behavior. When the first antistalking laws were passed in the early 1990s, efforts were undertaken to identify types of stalkers. The resulting typologies represent ways of theorizing about the nature of stalkers and the ways in which stalking cases can be managed and prevented. At least 25 typologies of stalkers have been reported but many have been highly speculative. Only a few have received substantive empirical investigation, and fewer still have received replication.

Typologies can be constructed along any number or content of dimensions. Such dimensions tend to represent either theoretically deduced features or empirically induced features. Some stalker typologies are simple, and others are complex. Typologies are considered simple if they have a single list of primary types and complex if they are hierarchically organized, or have two or more levels or axes of classification.

When typological systems are arrayed cross sectionally by underlying or classificatory dimension, four primary sets of characteristics emerge: *type of disorder* (e.g., physiological or psychological), *type of relationship or context* in which the parties involved began or continue contact, *type of primary motivation* (e.g., love or revenge), and *type of behavior* (e.g., harassing or violent). Some of these sets of characteristics translate into actual dimensions. For example, some typologies classify stalkers along ordinal continua that range from delusional to nondelusional, nonviolent to violent, or type of relationship (e.g., stranger to romantically involved). Other subtypes of stalkers in existing typologies focus on features such as victim characteristics (e.g., celebrity/public figure or neighbor), motivation of stalker (e.g., love or revenge), or risk of harm (e.g., low, moderate, or high).

Several early typologies revealed debts to the language of psychiatric and personality diagnoses. Early typologies reflected relatively deductive frameworks, in which existing criteria for psychological disorders were superimposed on the available empirical cases. For example, one of the earliest typologies identified three types of stalkers. *Erotomaniac* stalkers are characterized by delusions, typically nonbizarre, that a person is in love with the stalker. The object of obsessional harassment is likely to be of higher status than the stalker and is unlikely to have a prior relationship with the stalker. *Love obsessional* stalkers are similar to erotomaniac stalkers except that they are likely to have an additional primary psychiatric diagnosis. *Simple obsessional* stalkers are nondelusional harassers who have a prior relationship history, typically romantic, with the victim.

Simple Typologies

Simple typologies cluster multiple features of stalkers or stalking cases into an unsubordinated list of

types. Such typologies often produce labels for each type that are largely self-explanatory. For example, one largely speculative typology identified the following stalker types: celebrity stalker, lust stalker, hit stalker, love-scorned stalker, domestic stalker, and political stalker.

Simple typologies can classify stalkers or cases by type of behavior. One meta-analytically derived behavioral typology identified eight types of stalker activity. *Hyperintimacy* consists of inappropriate types of courtship or flirtation. *Interactional contact* involves efforts at establishing proximal or face-to-face conversation with the victim, whereas *mediated contact* involves attempts to establish contact through communication media. *Surveillance* behaviors attempt to monitor or acquire information about the victim. *Harassment/intimidation* activities are bothersome or stress-inducing behaviors, which range from insults, reputational assaults, regulatory or legal persecution, or simple excessive persistence. *Invasion* behaviors involve intrusions of the victim's personal space or property, which range from information theft to breaking and entering the victim's home. *Coercion/threat* activities represent verbal or nonverbal communications that imply potential harm to the victim or those people or things the victim values. Finally, *aggression and violence* is composed by all the forms of behavior that inflict or attempt to inflict injury or harm on the victim or those people or things the victim values. Any of these types of behavior can be enacted by the stalker directly or by third-parties, or *proxy* stalkers.

Another simple typological approach identifies the primary motivation that underlies a stalker's activity. The most typical motives identified in the stalking case literature involve *intimacy* motives, which range from abandonment or attachment loss, dependency, infatuation, jealousy, envy, love, obsession, reconciliation, relationship development, or sexual attraction. A second motivation complex involves *aggressive* intentions, which include anger, revenge, attack, control, possession, and intimidation. Other stalking cases seem more characterized by the stalker's *disability*, because of factors such as drug abuse or mental illness. Finally, some stalkers seem motivated by *task conflicts or issues*, in which a particular policy, decision, or action of the victim is considered problematic or in need of change. The main problem of simple

behavioral and motivational typologies is that most stalking cases reflect multiple and evolving patterns of stalker activity and intentions.

An early typology based on case studies of political stalkers identified hunters and howlers. *Hunters* are those who seek to harm or attack a political figure, whereas *howlers* are largely characterized by people who pursue, harass, or threaten, but are unlikely to carry out any actual attack. Howlers seem more threatening because they make their resentment or fixation known through their communications and attempted contacts with the victim. Hunters tend to hide their intentions or actions, and they are therefore more dangerous because the victim does not see the hunter coming.

An inductively derived typology used multiple victim-reported features to formulate a four-category typology of obsessive pursuers and harassers: harmless, low threat, violent criminal, and high threat. These types emerged largely from the differentiations of motive (hostile, love, controlling, and jealousy/freedom) and behavior (e.g., harassment, physical threat, illegal behaviors, and aggression toward victim's new partner).

One of the more detailed typologies in its case descriptions identified five types: rejected, intimacy seeking, incompetent, resentful, and predatory. These types are clearly focused mostly on motivational features. *Rejected* stalkers had a previous relationship with the victim and typically experience jealousy, infatuation, and possessiveness toward the victim. *Intimacy-seeking* stalkers are also infatuated but tend to experience erotomanic delusions regarding their victim. Such delusions fuel particularly persistent pursuit. *Incompetent* stalkers lack the social skills needed to pursue appropriately the mutual negotiation of relationship desired with the victim. Unlike intimacy-seeking stalkers, incompetent stalkers realize that the object of their pursuit may not be similarly interested in developing a relationship with the stalker. *Resentful* stalkers engage in a campaign of harassment in response to a perceived harm or transgression on the part of the victim. Such transgressions, as well as the relationship presumed between the stalker and victim, may be delusionally constructed. The object of pursuit is some form of revenge or vindication. The *predatory* stalker engages in organized and planned activity designed

to attack a victim, typically with sexual motivations entwined with the motive for such attack. The motives may involve paraphilia, power, and control, and the stalker may have a prior record of sexual offense. Applications of this typology to the classification of stalking cases produced a broad distribution across the following categories: rejected (35%), intimacy seeking (32%), incompetent (14%), resentful (14%), and predatory (5%).

Complex Typologies

One of the earliest typologies classified stalkers by their relationship to the victim and by the level of mental disorder. At the highest level of the typology is relationship context. Stalkers emerge from either nondomestic, or stranger or nonromantic beginnings, or from domestic romantic or familial beginnings. Each one of these categories then is subdivided. Nondomestic stalkers can be *organized* or *delusional*. Organized stalkers are characterized by forethought, intentionality, planning, and preparation, and they are likely to display reasonable reality-testing ability. In contrast, delusional stalkers will reveal imagined roles or scenarios in which the object of pursuit is prominent. Domestic stalkers can also be of a delusional subtype, in which the imaginary or imaginary scenarios involve significant romantic or familial content. Nondelusional stalkers tend to be persons who had some actual romantic relationship with the object of pursuit but cannot relinquish a persistent desire to continue contact, whether the motivations are amorous, harassing, antagonistic, or a combination of these.

Another dual-axis typology compares the motives of the stalker (affectionate/amorous or persecutory/angry) across relationship types (personal, professional, employment, media, acquaintance, or stranger). Affectionate/amorous stalkers are primarily seeking romantic intimacy, although such feelings can shift to anger or aggression if such pursuits are rejected by the victim. Persecutory/angry stalkers tend to seek redress of an attributed transgression or injury. Such stalkers are more likely to have multiple victims and psychiatric disorders.

Another complex taxonomy of stalkers uses duration of stalking, victim apprehension, actual victim risk, stalker motive, and ability to intervene

to differentiate four types, as follows: ex-partner (harassment/stalking), infatuation (harassment), delusional fixated (stalking), and sadistic (stalking). *Ex-partner* harassment and stalking cases are long-lasting cases, which are motivated by resentment, produce victim fear and anger, and represent high risks based on proximity and personal contexts. *Infatuated* stalking cases tend to be short-term in duration, are motivated by love or attraction, lead to victim annoyance or embarrassment, and reflect relatively low-level risks to the victim. *Delusional fixated* stalking cases involve long-lasting cases, which are motivated by often incoherent obsessions, blatantly inappropriate forms of communication and contact, and victim fear and bewilderment. These cases range from moderate (i.e., less dangerous) to high (i.e., dangerous) risks to the victim. *Sadistic* stalking cases represent long-term cases, in which the motive is control and predation, the victim typically experiences fear and feelings of helplessness; in this scenario, the risks to the victim are high.

The typology that was developed on the basis of the largest sample of stalking cases is formulated along the two dimensions of relationship (intimate, acquaintance, or stranger) and context (private or public). These axes produced two complex types: Type I consists of stalkers who had a previous relationship with a private figure context. Type I stalkers comprise the following two subtypes: *intimate* stalking, in which the victim is a former partner, and *acquaintance*, in which the victim was a co-worker, friend, client, customer, or other non-romantic or nonfamilial affiliation. Type II stalkers, strangers, have no prior relationship or only incidental contact with the victim. Two subtypes for Type II stalkers consist of *public figure* contexts, in which celebrities or politicians, or other publicly accessible person is pursued, and *private figure* contexts, in which the victim has relatively little public exposure and no relationship to the pursuer, but nevertheless becomes an object of the stalker's fixation. This typology was derived from an examination of more than 1,000 stalking cases, and it produced a distribution of 50% intimate, 27% public figure, 13% acquaintance, and 10% stranger stalkers. Type I stalkers tended to have more female targets (91% vs. 77%) than Type II stalkers, and these individuals use more threats (79% vs. 26%) and violence (69% vs. 10%),

whereas Type II stalkers tended to have more male targets (29% vs. 10%) and were more likely to be diagnosed as psychotic (26% vs. 13%).

Limitations of Typologies

As useful as typologies are for a general understanding of stalking, they tend to suffer from several limitations. First, they are rarely grounded in a coherent theory of stalking activity. Second, although many typologies take into account the relationship of the stalker to the victim, existing typologies are entirely focused on the stalker as an individual, rather than the features of the *stalker-victim* interactional pattern. Third, with one or two exceptions, there has been a lack of replication, publication of coding details, or explicit validation of categories. Fourth, whereas the more complex typologies may better reflect the complexity of the phenomenon, they also tend to produce more impure categories, such that given features occur in multiple categories. Fifth, empirically based typologies are based on biased samples, which are typically derived from counseling or forensic sources. Such cases are likely to represent more serious or violent cases, thereby excluding many of the more mundane and unreported types of cases. Sixth, another source of bias is the potential for a Western, Anglo orientation, given that little stalking research has been reported in non-English-speaking cultures. Finally, stalking cases often last months or even years, and consequently, few stalking cases are likely to be validly characterized by a single typological characterization.

STALKING

It was during the 1980s that stalking first became recognized as a crime in the United States. After the highly publicized stalking and murder of actress Rebecca Schafer, as well as several other stalking murders and attempts, we began to think of stalking as a serious crime that the country needed to legislate and enforce. Legislation criminalizing stalking followed these tragic, and potentially foreseeable, events. California was the first state to adopt legislation that defined stalking as a criminal offense (in 1990). After the U.S. Congress enacted legislation that required the Attorney General to research and develop a model anti-stalking code, other states followed in short order, and currently, all 50 states have similar stalking classifications.

It is staggering to consider how prevalent stalking is, yet it has remained relatively unnoticed by

scholars and practitioners until recently. The National Center for Victims of Crime estimates that 1 of 12 women and 1 of 45 men will be stalking victims during their lifetimes. Thus, during any given year, nearly 1 million women and 400,000 men experience the crime of stalking. Furthermore, there is no possible way to estimate the number of secondary victims of stalking: the friends, family, co-workers, and neighbors who may experience fear, injury, threats, and harassment simply by virtue of living in the same locations, having contact with, and being important to the primary victims of stalking.

Equally interesting is the difficulty policy makers have with its definition. Undoubtedly, some of these difficulties stem from the orientation of the criminal justice system: that one is innocent until proven guilty, and one cannot be arrested without actually *doing* something illegal. Prior to stalking legislation, a victim might have reported her stalker to the police only to be told that they could not do anything because “he (she) hasn’t actually done anything wrong yet.” Now, although specifics vary across states, most statutes include definitions that convey the idea that stalking is made up of tangible *behaviors*. As such, these tangible behaviors, such as when a person follows, observes, harasses, or threatens another repeatedly, are, in and of themselves, illegal and should not be viewed as harmless preludes to future illegal behavior.

The Problem of Definition

Currently, most stalking statutes incorporate several elements, as follows: (1) the behavior is a course of conduct; (2) it is viewed as unwanted and harassing—that it causes substantial emotional distress and serves no legitimate purpose; (3) the offender must pose a credible threat to the safety of the victim, his or her family, or friends; and (4) most recently, *cyberstalking* has been added to the growing ways in which stalkers harass and frighten their victims.

There are problems when interpreting these definitions and behaviors of stalking. For one, the notion that the behaviors represent a “course of conduct” can be difficult, because how long does it take, how many acts does it take, for certain behaviors to create a “pattern” or “course” of actions? Victims may have different interpretations regarding

how long the stalking goes on before they actually label what is happening to them as stalking. Law enforcement officers may also have interpretations concerning how many incidents make up a trend. These varying interpretations can make it difficult to pinpoint the moment when a person stops being just irritating and becomes a stalker; when the conduct moves from legal but inappropriate to illegal. And, of course, it can prolong unfortunate and potentially dangerous circumstances when victims and law enforcement officers have different interpretations of this element.

Furthermore, the terms *credible* and *threat* are both complicated. For example, how serious does one have to be to be considered credible or reasonable? Presumably, standards for reasonable fear would be different for males and for females, or for timid people and more aggressive people; which standard should we use, or should they be different? Some stalkers say things that on the surface seem romantic to an outsider, but to the victim, the underlying menace in the stalker's voice makes the discussion much more threatening. In addition, must threats be verbal? Could threats be written? Do they have to be clear and direct, or can they be implied? Can threats take the form of a rose left on the victim's car windshield? To an outsider this gesture may seem romantic, the message one of begging for forgiveness; whereas to the victim, the message may clearly be "I know where you are. You can't hide from me."

In the end, the federal government and most states have passed antistalking laws that authorize the arrest of persons who repeatedly follow or appear within the site of another, approach or confront another person in a public or private place, appear at the workplace or home of another, enter or remain on a person's property, call a person on the phone, or send mail or email to another. States have also acknowledged that the behavioral pattern of stalking is typically characterized by increasingly more serious actions, and as such, these states have legislation that places stalking behaviors on a continuum from misdemeanor to serious felony.

Offenders

Stalking is most often characterized as a crime of obsession, and offenders are viewed as having

often severe psychological disorders or psychoses. Many scholars typify stalkers into three categories: simple obsessional, love obsessional, and erotomania. Using this typology, the simple obsessional is the type who stalks his or her spouse, lover, or former boss. The love obsessional is typically a male who stalks a stranger (possibly a celebrity) and professes inappropriate romantic notions. Finally, the erotomaniac is typically a female who stalks a man she believes loves her. She reinterprets his responses to her to support her delusions. In this case, it is the latter two types of stalkers who may have psychological disorders. Other typologies of stalkers include the following: the *intimate* stalker who wants to (re)establish a permanent romantic union; the *rejected* stalker who pursues his or her victims to reverse or avenge a rejection (e.g., divorce, separation, and termination); and the *predatory* stalker who spies on his or her victim to plan an attack—usually sexual—on the victim. In this typology, any of the stalking types may be persons who are psychologically unbalanced or they may be normal, just inappropriately and unflaggingly relentless.

Stalkers use a wide variety of strategies. Depending on the type of stalker, he or she may use courtship behaviors like professing love or begging the victim to return. The offender may use surveillance techniques such as following the victim, driving by the victim's home or place of work, spying on the victim, tapping phones, or otherwise listening in on the victim's conversations. Most stalkers use threats, either direct or implied against victims. These may include threatening to kill the victim; breaking in or vandalizing the victim's car, home, or property; entering the victim's home without permission; verbally abusing the victim; threatening to harm the victim; threatening the victim with a weapon; threatening suicide if the victim does not comply; theft; opening or closing financial accounts; taking money from financial accounts; and using victims' credit cards. Stalking often escalates into violent behaviors such as physical assault, preventing the victim from leaving some place, sexually assaulting the victim, or murdering the victim. Other types of behaviors that are typical of stalkers are showing up at the victim's home or work, repeatedly

telephoning, contacting the victim's family, and leaving written messages.

Victims

Women are primarily the targets, and their stalkers are usually ex-partners who cannot accept the conclusion of the relationship. Typically, the stalking behaviors start right after the conclusion of the relationship, which was likely characterized by abuse. The Federal Bureau of Investigation estimates that about one third of female victims of homicide were previously stalked by their killers.

Victims of stalking (both male and female) are unique from many other types of crime victims. They experience a crime that is ongoing, rather than having a definite beginning and end. Many victims experience great confusion because the stalking often incorporates romantic gestures, even while still being threatening, and the victim may have once loved the stalker. Nonetheless, stalking is a crime that produces extreme stress, fear, and hysteria. The stalker may seem to be everywhere; she hides but he finds her. He may be whispering sweet nothings to her, but he may also be ranting abuse as well. Victims try to get help, but it is often not particularly effective, and all the while he or she continues to experience stalking. Stalking causes great emotional distress. Victims may experience denial, guilt, shock and confusion, irritability, fear, anxiety, phobias, panic attacks, anger, depression, flashbacks, difficulties with concentration, posttraumatic stress disorder, health problems, sleep disturbances, or alcohol/drug use or abuse. Research by the Bureau of Justice Statistics (BJS) shows that victims' worst fears resulting from the stalking include (in order of notation by victims) not knowing what would happen next, thinking that the behavior would never stop, experiencing bodily harm, having their child(ren) harmed or kidnapped, having a family member harmed, experiencing loss of freedom, being killed, having a current partner harmed, or losing their minds. At the beginning of the stalking or harassment, victims typically felt annoyed or angry, but these feelings quickly moved to feeling frightened, helpless, depressed, sick, or suicidal.

Research findings suggest that stalking victims are not terribly likely to take actions to protect themselves or to stop the unwanted behaviors.

However, when they do, the most common actions they take are to change their usual activities (e.g., staying with family, taking time off from work or school, avoiding family and friends, changing route to work or school, changing or quitting job or school, and altering their appearance). Victims may also take protective actions such as installing caller ID/call blocking; changing their phone number; changing locks; getting a security system; getting pepper spray, a gun, or other weapon; or taking self-defense classes. Finally, victims may change their personal information, such as their email addresses or social security numbers. Similarly, stalking victims were not likely to seek help from others. However, when they did, it was likely to be from family and friends or their bosses. Victims also may ask people not to release their information.

Patterns

Researchers tend to find that the typical victims of stalkers are women (~70%) and that women are most likely to be stalked by a spouse or ex-spouse. Men are far less likely to be stalked, and when they are, it is likely to be by a stranger or acquaintance. Having said that, research indicates that although women may be more likely to be stalked, both men and women are equally likely to experience harassment. Regarding the relationship between the offender and victim, research highlights that most stalking victims (males and females together) are stalked by someone they know but who is not an intimate or ex-intimate partner. To elaborate, 45% of stalking victims were stalked by a friend, roommate, or neighbor. It may have been someone they knew from work or school, a casual acquaintance, or a relative. The next most likely relationship of the offender to the victim was an intimate or former intimate such as a spouse, a former spouse, or a boyfriend or girlfriend. Last, victims may have been stalked by a stranger. Interestingly, approximately 17% of stalking victims did not know who their stalker was. Nevertheless, according to the BJS, nearly three in four stalking victims knew their stalker in some capacity. Furthermore, male and female stalking victims were equally likely to report the offense to the police.

In 2008, the Supplemental Victimization Survey (a subset of data from the National Crime

Victimization Survey) reported on the stalking victimization experienced by members of U.S. households in the previous year. Many patterns emerged. The most likely age group of stalking victims was 18- to 19-year-olds who comprised nearly half of those individuals who indicated they had been stalked. The next most likely age group was 20- to 24-year-olds with only slightly fewer in proportion. Persons who identified as being a member of more than one race were the most likely stalking victims (49%). American Indian/Alaskan Natives were the next most likely victims (33%), and Whites and Blacks followed with proportions of 24% and 23%, respectively. Divorced or separated individuals were those with the greatest risks for stalking victimization regarding marital status, and household income emerged with a telling pattern: Those who were the poorest (incomes less than \$7,500) had the highest rates of stalking victimization.

Regarding length of time, statisticians indicate that nearly half of stalking victims experienced at least one unwanted contact per week, and 11% of victims said they had been stalked for 5 years or more. The largest group of victims, however, experienced stalking for 6 months or less.

The form stalking takes is another question and concern. The report found that one in four stalking victims reported some form of cyberstalking, such as email (83%) or instant messaging (35%). Stalking victims also reported that they had their property damaged, had their residence or car illegally entered, had their financial accounts tampered with, had their credit cards used without permission, or experienced some other theft. Physical harm typically came in the form of being hit, slapped, and knocked down, but victims were also choked, strangled, attacked with weapons, chased or dragged with cars, and raped. Furthermore, victims indicated that stalkers also attacked family members, co-workers, pets, and the victims' children. The most likely weapon used in physical attacks was a knife.

The consequences of stalking can be significant. More than half of stalking victims lost 5 or more days from work. Many victims reported they feared bodily harm to themselves, and only slightly fewer were worried about the safety of a child or other family member. Ten percent of stalking victims feared their stalker would kill them. About 40% of victims revealed their stalkers threatened

the victims' families, co-workers, or family pets. There was also likely to be a financial impact on stalking victims as they had to pay for things such as attorney fees, damage to property, child care costs, moving expenses, or changing phone numbers. Victims may also have lost pay because of missing work.

Cyberstalking

Cyberstalking is a relatively new phenomenon. With access to a computer, stalkers' identities and whereabouts can remain undetected. They can engage in stalking and harassment behaviors easily and cheaply, and they can wreak havoc on the lives of victims with little effort. Online, stalkers can get to their victims via chat rooms, message boards, discussion boards, email, instant messaging, texting, posting pictures or information on Web sites, and hacking into financial, social networking, and professional accounts. In these contexts, the cyberstalker can seem to be everywhere. He or she can post messages that seem to be from the victim, and can give out personal information about the victim so that others can contact or harass the victim. Stalkers can text their victims frequently indicating they know where their victims are. Cyberstalkers can hack into victims' school accounts and change their class schedules and post discussion messages that look like they are from the victims. The victim may have his or her accounts frozen, drained, closed, or altered. Victims have had various types of accounts opened in their names. For example, stalkers can open an email account in the victim's name and send inappropriate emails to co-workers and friends. Victims have had pictures of themselves that have been altered so that they seem to be naked posted on message boards where their friends, families, and co-workers may see them. Or, these pictures may be posted with personal information and solicitations to strangers. A computer-savvy stalker can set up a program to have hundreds, if not thousands, of emails sent to his or her victim daily. He or she can hack into a victim's bank account and cancel automatic bill payment. In essence, cyberstalkers, with only a small amount of personal information about the victim can steal the victim's identity and completely destroy his or her life. It is obvious that even though cyberstalking is a new form of stalking, the methods and

consequences can, and are, just as dangerous and devastating as more traditional forms of stalking.

Police Responses Versus Victims' Responses to Stalking

Typical or usual (and completely understandable) victims' responses often jeopardize their cases as well as their positions and significance as "victims" in the eyes of the criminal justice system. To illustrate, many victims engage in what are called acquiescence strategies. These involve assenting to their stalkers to some small extent so that "he would stay cool." These may be viewed by law enforcement as the victim being unsure of what she wants or leading the stalker on. Another example is that many stalkers engage in "courtship"-like behaviors (e.g., leaving a rose on the windshield of the victim's car, professing love, or begging the victim to return). Although the victim is aware of the true meaning and threatening nature of these "romantic" displays, others, such as criminal justice personnel, may recognize these seemingly insignificant behaviors as nothing to worry about or get so uptight about. As expected, these issues regarding the definition of stalking negatively impact victims' experiences with the criminal justice system as well as the ability of criminal justice personnel to protect the victim adequately. As such, many victims of stalking do not report their harassment to the police, or do so only minimally.

Responses to Stalking

Given the difficulties in enforcing stalking statutes, victims need to be provided with concrete information about how to plan for their safety. Several types of strategies have been suggested by researchers and law enforcement officials. And, although these strategies need to be empirically tested for their effectiveness, until that time, they are the best strategies "those in the know" have developed. Such strategies include alerting friends, family, and co-workers about the situation so that the stalker cannot manipulate them. Victims should obtain a restraining order, even if only to show officials they are serious about the stalking being unwanted. Victims should alter their routines and learn self-defense. They should establish

security measures at their residence, use an answering machine and keep all messages from their stalkers, establish a separate phone for their personal calls, and have the phone company install a trap on their phone so hang-ups and harassing calls can be traced. If victims have garages, they should use them and close the doors so that the stalker does not know whether they are home. They should put all bills in fake names, and set up accounts in fake names (this is legal as long as the companies with whom the bills and accounts are with know the situation and what the account holder's real name is). Finally, they should avoid places that the stalker knows they frequent, and if they have children in common and visitation is required, they should have custody exchanges take place at the police station or via a third party. Practitioners should have these suggestions at the ready for stalking victims and researchers should empirically examine strategies to assess their effectiveness at ending the stalking more quickly, with less violence, or with less escalation in injury and damage.

STALKING, MEASUREMENT OF

Stalking is a complex behavior and is not easily studied. Stalking can generally be described as a pattern of unwanted contacts and harassing behaviors directed at a specific person that can induce fear and distress. Because the meaning of the stalking behaviors is often contextual and subjective (usually these behaviors have special significance known only to the offender and victim), objectively measuring these behaviors is difficult. Attaining reliable and consistent data on the prevalence and incidence of stalking is challenging because inconsistent measures are used to identify stalking behavior. Despite this difficulty, research on stalking has illuminated much of the complexity, nature, and extent of the crime. This entry outlines the important areas of focus in stalking research, several methodologies used, some challenges associated with studying stalking, and recommendations for the future.

Researchers have attempted to identify the frequency of stalking, the behaviors and characteristics of stalkers, the impact of stalking behaviors on victims, victim responses, actions taken by criminal justice and mental health systems, and correlation of stalking with other crimes. Stalking research methodologies vary, but it has been studied through epidemiological analysis, general surveys, case studies of forensic samples of stalkers, and self-reports of stalking victims. Although most stalking research is completed with sample populations of victims or offenders involved with the criminal and civil justice systems, several epidemiological reports have stimulated researchers to look at nonforensic populations of stalkers, such as university and college students.

Survey research involves asking standardized questions of a large number of respondents and may be done through questionnaires or individual interviews. The first large-scale survey on stalking in the United States was the National Violence Against Women Survey, which measured lifetime prevalence rates of stalking. Patricia Tjaden and Nancy Thoennes developed a measurement for stalking victimization behaviors. This important tool also measured the extent of fear stalking victims felt as well as the frequency of experiences specific to stalking behaviors.

Descriptive epidemiologic studies are document reviews or large population surveys. These provide information about the occurrence of stalking in a specific population or its subgroups, such as Bonnie Fisher and Francis Cullen's National College Women Sexual Victimization Study. When researchers review available records, they do not necessarily interact directly with subjects. Instead, researchers examine and analyze narratives, stalking arrests records, and other court records to find commonalities or trends that can be used to identify populations and subgroups at high and low risk for stalking, as well as to provide insights on which to base future studies.

Case studies in stalking research focus on known stalkers or self-identified victims to provide information on the context of stalking, predictors of stalking, or cues to managing stalking behavior. Case studies have helped researchers assess the types of stalking behaviors, the frequency and intensity of the behaviors, the nature of attachment of stalkers to their victims, and the motivation for the stalking actions.

Studies that measure the experiences of stalking victims often examine the impact stalking has had on their lives and the actions victims have taken to stop or ameliorate the problem. Through case studies and epidemiological reviews, researchers have theorized various classification systems or typologies for different kinds of stalkers. Other research has examined the poststalking interventions that criminal justice and social service organizations have taken to assist victims or treat the stalking offender. Correlations between stalking and other interpersonal crimes have also been explored through case studies on intimate partner violence and sexual assault.

Developing scales to predict a stalker's future use of violence is another area of research. These studies attempt to gauge the threat of future violence by analyzing contextual factors, such as characteristics of victims and stalkers, stalking behaviors, and the nature of the relationship between the stalker and victim, to formulate a structured risk-assessment tool. These structured risk-assessment tools can be clinical guides or actuarial measures: Structured clinical guides identify potential areas of concern or create checklists to guide clinical assessment of future risk for violence; actuarial instruments are guides that assign specific significance to the different variables to assess the risk.

Studying stalking entails several challenges. Because of the high cost and complexity involved, community-based studies on the prevalence of stalking are scarce. Other studies are limited by a lack of diversity or the size of the sample population. Researchers usually create their own definition or operationalization of stalking, and this has resulted in no consistent or standard measurement in identifying stalking victims or classifying stalkers. Measurement scales vary among behavioral indices, self-classification schemes, and stalking perpetration scales. For example, studies on stalking behaviors might consider "obsessive relational intrusion" or "unwanted pursuit behaviors" whereas others outline "harassment in abusive relationships." Few replication studies of previous research have been conducted using the same stalking measurement. Risk assessments of potential stalking-related violence are limited by a lack of prospective studies.

Although stalking research has not yet provided consistent measurement for prediction, assessment, or even management of stalking behaviors, it has raised awareness, increased our understanding, and provided necessary guidance for those working with stalkers or stalking victims. Having a better understanding of stalking is critical, as it can reveal opportunities for intervention, aid in offender accountability, and most importantly, enhance victim safety.

STALKING LAWS

Stalking legislation in the United States has significantly evolved since the first criminal statutes were passed in the early 1990s. As lawmakers across the country began to write legislation, they struggled to define and address adequately the complicated, often-evolving crime of stalking. Nearly 20 years later, legislators are still revising statutes, and the criminal justice system is still adapting its approaches to the crime.

When California enacted the first criminal stalking statute in 1990, many criminal justice practitioners and legislators were just beginning to understand the nature and impact of stalking. During the last 18 years, research and practice have yielded statistical and anecdotal data that show the magnitude of the crime: An estimated 1.4 million people are stalked annually in the United States, and 1 in 12 women and 1 in 45 men

will be stalked in their lifetime. Most stalkers are male, and are most often known to their victims. The toll of stalking on victims can be great. Many victims experience anxiety, insomnia, social dysfunction, severe depression, and posttraumatic stress disorder. They may lose time from work or even be unable to return to work. Some victims incur additional financial costs because they relocate to escape their stalker. As knowledge about the crime has increased, jurisdictions across the country have worked to clarify and strengthen their stalking laws.

History

Stalking legislation began in 1990 in Orange County, California, after four women had been murdered despite the restraining orders they had obtained against the men who later killed them. Municipal Court Judge John Watson, after reading a newspaper article about the powerlessness of law enforcement to prevent these murders, drafted the first stalking statute and presented it to a state senator for consideration. Watson's actions, coupled with national media attention of the murder of actress Rebecca Schaeffer by her stalker, led the California state legislature to enact CA Penal Code Section 646.9 "Stalking" that same year. The law made it a felony to cause another, or their family, to be in reasonable fear for their safety and carried a prison sentence.

Jurisdictions across the country quickly followed suit by enacting stalking statutes of their own. By the end of 1993, all 50 states and the District of Columbia had enacted laws that addressed stalking, although two states addressed stalking behavior under broader statutes such as harassment or terrorizing. In 1996, U.S. Congress made interstate stalking a federal criminal offense. Many American Indian/Alaska Native tribes, the U.S. Territories, and other common-law jurisdictions also criminalized stalking in their legal codes. Criminal justice practitioners and victim advocates (primarily domestic violence advocates) have been encouraged that many of these laws criminalized frightening and threatening stalking behaviors that had previously been dismissed as noncriminal.

Most stalking statutes passed in the early 1990s included a definition of stalking and a penalty for committing the crime. The statutes often defined

stalking as involving a "pattern of behavior." Jurisdictions varied widely, however, on how they choose to define this pattern of behavior or course of conduct. Some included a list of prohibited behaviors (e.g., following, threatening, or repeated harassment), and others simply stated that it is illegal to conduct a pattern of behavior against someone that would cause that person to feel fear.

Model Codes

National Institute of Justice Model Code

In 1993, Congress, to support and guide states' efforts to enact stalking statutes, asked the National Institute of Justice (NIJ) at the U.S. Department of Justice to create a model stalking code (NIJ Model Code). NIJ and other national partners worked with criminal justice practitioners, victim advocates, and legislators across the country to address the many legal issues that may arise when a jurisdiction enacts a stalking statute. Because the NIJ Model Code was published so soon after the first statutes were enacted, there was little time to test the stalking statutes (through appeals of criminal convictions) and decipher the exact legal issues that would emerge from those appeals.

Although the NIJ Model Code gave much-needed help to jurisdictions seeking to enact stalking statutes, in many states few stalking cases were investigated and prosecuted in the years immediately after the new statutes were passed. Law enforcement officials cited a lack of reporting by stalking victims and a lack of direct evidence for prosecution in the stalking cases that were reported to them as reasons for the low number of investigations and prosecutions. Prosecutors found it challenging to prosecute an offender for stalking; the fact-finder (judge or jury) often knew little about this crime.

Several of those cases that were prosecuted and resulted in a conviction were appealed to higher state courts in an effort to overturn the conviction, a part of the statute, or the statute as a whole. Appeals during this time often involved challenges to the constitutionality of stalking statutes. Offenders argued that their jurisdiction's statute was either overly broad (that the statute was written to include too many behaviors that are legal) or vague (that the statute was not written clearly

enough for the average person to understand what behavior is criminalized).

Other appeals pertained to the sufficiency of the evidence used against the offender to convict him or her of stalking. Offenders often argued that there was not enough direct evidence of a fear-inducing pattern or behavior or that the behaviors committed by the offender did not meet the jurisdiction's definition of stalking. Appeals courts sometimes struck down parts of state statutes. Such court rulings, along with requests from criminal justice practitioners and victim advocates who continued to observe cases being ignored, prompted many state legislators to begin revising their existing stalking statutes.

National Center for Victims of Crime Model Code

In January 2007, after years of requests from various jurisdictions on specific ways to strengthen their stalking statutes, the National Center for Victims of Crime (NCVC) released "The Model Stalking Code Revisited" (NCVC Model Code). The NCVC Model Code was informed by new empirical research on stalking and the experiences and knowledge of the staff of the national Stalking Resource Center, which is a project NCVC launched in 2000 to raise national awareness of stalking and to encourage the development and implementation of multidisciplinary responses to stalking in local communities across the country. The Stalking Resource Center has provided training and assistance to thousands of victims, victim advocates, and criminal justice practitioners, and it has learned the various problems jurisdictions were facing with their existing stalking statute, including lack of awareness of statutory requirements and lack of enforcement.

The NCVC Model Code aims to address these statutory problems by clarifying the definition and punishment sections of a stalking statute. For example, in clarifying the definition of stalking, jurisdictions can address the emerging use of technologies or other new behaviors in stalking cases. In clarifying the punishment section of the statutes, jurisdictions can show that they take stalking seriously by enacting appropriate punishment for the crime.

One major issue addressed in the NCVC Model Code is the importance of eliminating the "credible

threat" requirement in many definitions of stalking. States often require prosecutors to prove that the offender had made a "credible threat" (generally defined as a threat made with the intent and apparent ability to carry out the threat) against the victim to prove that the accused had committed the crime of stalking. However, research and practice have proven a strong connection between stalking and other intimate partner crimes, such as domestic violence and sexual assault. In intimate relationships, threats often may be understood only by those in the relationship, not by outside parties, and it was often difficult for prosecutors to prove to a judge or jury that certain behaviors constituted threats. For example, if a stalking victim who has relocated in an attempt to escape her stalker finds a rose in her car—the same type of rose she has received from the offender in the past—the victim is likely to perceive the rose as a message that she has been found and is in danger. However, someone unaware of the history between the victim and the offender may view the rose as a harmless gesture. Therefore, the NCVC Model Code recommended removing the credible threat requirement from stalking statutes.

With the help of the NIJ Model Code and NCVC Model Code, states have much more information and education to help them enact stalking statutes that meet the needs of stalking victims and hold offenders accountable for their criminal behaviors. Informed by the Model Codes, many states have amended their stalking statutes to address the use of technology (e.g., telephones, spyware, and global positioning systems) as part of the "course of conduct" of stalkers—an element of the crime that was almost entirely absent from early stalking legislation. Many states have acted to include the standard of "fear for the safety of a third person" in addition to fear for the victim's own, recognizing that stalkers often deliberately target those close to the victim to terrorize the victim even more.

Enhancing Responses to Stalking

Although jurisdictions have worked hard for the last 20 years to enact statutes to cover the criminal stalking behaviors identified in their communities, stalking victims and the criminal justice system still face many challenges in dealing with the crime.

One challenge is the continued lack of understanding of the crime of stalking and awareness of stalking laws among those who encounter stalking victims. Despite the availability of stalking training for criminal justice practitioners and victim advocates in many jurisdictions, some jurisdictions cannot afford the training or have not made such training a priority. Even when professionals are trained, high turnover rates in first-responder positions (patrol officers and crisis line workers) often leave many professionals uneducated about the crime and the seriousness of stalking, and leave stalking victims with little information and little recourse.

Another challenge is the hesitation of some prosecutors to prosecute stalking cases either because they do not believe they have enough direct evidence to prove the case or they are unwilling to risk losing at trial. Finally, judges and juries (public citizens) often receive little to no training or information about stalking and its seriousness.

In some jurisdictions, enhanced stalking statutes have resulted in increased arrest and prosecution of stalkers. However, well-written stalking laws and effective criminal justice responses often do not stop the stalking behavior. Therefore, successful responses to stalking require a community-wide approach that ensures an effective criminal justice response via continued review, analysis, and enhancement of criminal stalking statutes, along with legal, medical, mental health, and advocacy services to support and enhance the safety of victims of stalking. Together, these multifaceted coordinated community responses to stalking can help ensure that stalking laws achieve their goals of enhancing victim safety and increasing offender accountability.

STOCKHOLM SYNDROME

Stockholm syndrome is a psychological and emotional process whereby the abused comes to identify with the abuser. In some cases, a bond forms between a victim and a victimizer whereby the victim actually feels a strong attachment to his or her abuser. The syndrome was initially identified as the result of events that took place at a bank robbery in Stockholm, Sweden, on August 23, 1973. The reporter who documented the infamous robbery in Stockholm in great detail noted that the hostage takers acted with both brutality and kindness. A commissioner who entered the bank to check the status of the hostages a few days into the ordeal noted that the environment was peculiar, in that the hostages were hostile toward him and almost comfortable with their abusers, engaging in banter, light conversation, and even smiling. The hostages reported that the small kindnesses afforded them were seen as gifts, which they appreciated. They saw their captors as merely responding to the threat of police. Hostages later reported confusion in these feelings of gratitude, even though at the time they seemed rather genuine.

Classic Stockholm Syndrome

During a bank robbery, three women (Birgitta Lundblad, Elisabeth Olgren, and Kristen Ehnmark) and one man (Sven Safstrom) were held captive by two male bank robbers with extensive criminal histories. The hostages were held for 131 hours, during which they developed strong attachments to their captors, coming to hold empathetic and

protective feelings toward them; the women eventually viewed police as more threatening than their captors. The relationship between the victims of the robbery and their captors persisted beyond captivity; some victims reported they continued the relationship for years after the actual event. Dee Graham, Edna Rawlings, and Robert Rigsby report that, in 1985, a leading American paper reported that two of the female captives were engaged to their captors.

This behavior response pattern has come to be known as Classic Stockholm Syndrome. Indications that Stockholm syndrome is present include (1) positive attitudes and emotions by the captives toward their captors, (2) negative attitudes and emotions by the captives toward the police and other authorities trying to win their release, and (3) positive attitudes and emotions by the captors toward their captives.

Graham's Stockholm Syndrome

Graham, Rawlings, and Rigsby proposed several paradoxes of the syndrome. They argue that fundamental differences are found between what the hostages perceive and how behavior is interpreted by outsiders to the situation. One of the most common features of the syndrome is that often, the hostages feel gratitude toward their captors for letting them live. In some cases, this can be interpreted as having their lives given back to them. This feeling is juxtaposed against the perspective of the outsider who believes that no one has the right to willfully threaten or take another's life. The syndrome is also characterized by the hostages who find it difficult to feel anger toward captors. Outsiders expect the hostages to express anger for being terrorized and being held against their will. In addition, the hostages view captors as kind, with the captors' small kindnesses superseding the psychological impact of terror. Outsiders view captors as indifferent to hostages' and others' suffering.

Individuals who are taken captive and develop an affinity for their captors do not take advantage of opportunities to escape, as opportunities are not viewed as such. Outsiders find this difficult to comprehend as opportunities for escape are more visible from outside the situation. This is hampered

by the fact that even if offered a route of escape, many captives with the syndrome will not take advantage of it expressing concern for the people who have taken them hostage. Outsiders view this concern as unwarranted. Another paradox is that the captives come to see the captors as "good guys" and may come to think of the police as threatening, contrary to the public's perception. The captives become sympathetic to their captors and may refuse to testify against them. In some cases, captives have tried to fundraise for their captors' legal costs. This runs contrary to the public view that those who engage in this kind of illegal activity should be held accountable, often to the maximum sentence available, and that their captives' sympathy is based on a relationship that is not real.

Finally, many captives do not feel safe after their release. Despite their feelings of sympathy toward their captors, once released they fear that the captors will come back and hold them hostage again. Outsiders understand that the hostages are safe once they are released and fail to understand the anxiety that captives feel after the ordeal has passed.

In an actual hostage negotiation situation, the development of the syndrome between captives and captors is encouraging to those involved in negotiating the release of hostages. The presence of protective feelings from either the hostages or their captors may mean that victims have been somewhat successful in bonding with their captors. If bonds are formed between these two parties, it is widely thought that this may increase the hostages' chances of survival.

Extending Stockholm Syndrome Beyond Hostage Negotiation Situations

Graham, building on these ideas in 1987 but published in *Loving to Survive* 7 years later, extended the idea of Stockholm syndrome to other groups where there was an indentified victim and the presence of intense, long-term abuse. Graham, Rawlings, and Rigsby examined other possible groups to determine whether there was evidence of similar facets of the syndrome. They reviewed records of concentration camp prisoners, cult members, civilians in Chinese Communist prisons, pimp-procured prostitutes, incest victims,

physically and/or emotionally abused children, battered women, prisoners of war, prisoners, hostages, and—in some cases—children and partners of alcoholics. In all groups, there was evidence of bonding when the four conditions were present.

The first of these was that there was a genuine perceived threat to one's own survival and that there was a strong belief that the captor was willing to carry out threats. Second, the captive perceived some small kindness by the abuser toward the abused and it was appreciated. Third, the victim was isolated, and views of outsiders to the relationship were dissuaded leaving only the captors views to be adopted. Finally, the abused had a genuine belief that they could not escape their situation.

The abuser creates an intense relationship, based on violence and manipulation, forging a similar situation as evidenced in the Stockholm bank robbery. Once a bond is established, victims become protective towards their captors, and often try to protect their abusers, despite the actions of the abusers. Outsiders may find the behaviors of victims who have bonded with their abusers difficult to understand, not comprehending how a bond could form under these conditions.

Stockholm Syndrome and Intimate Partner Violence

Using the example of intimate partner violence, it is often confusing to friends, family, police officers called to a dispute, and so on, when the abused tries to protect the abuser, even though it is clear that the victim of intimate partner violence is in grave danger. The victim may attempt to explain the violence he or she has experienced by using the abuser's reasoning, such as blaming the abuser's stressful employment situation or blaming oneself for aggravating the abuser, thereby causing the abuser to injure the victim. This reasoning is often questioned by outsiders as irrational, but understood using elements of Graham's Stockholm Syndrome. The abused has bonded with the abuser and has served to identify with their abuser as a survival technique. Proponents of Graham's theory predict that removal from the abuser is necessary, but it will cause anxiety for the abused similar to the aftereffects of those

identified by the syndrome. Using this example, victims of intimate partner violence may report feeling sympathy for their abusers, as well as not feeling safe and a fear that the abuser will return, even after the abuser has been arrested and incarcerated.

STRATEGIC APPROACHES TO COMMUNITY SAFETY INITIATIVE (SACSI)

Efforts to combat crime using partnerships have become commonplace today. One early initiative in the United States, the Comprehensive Communities Program (CCP), was implemented in 1994 as a partnership-building endeavor aimed at fighting crime and improving the quality of life in communities. A total of 15 communities participated in the project. The major key to CCP was to use a problem-solving approach which included a wide array of community individuals, agencies, and groups. Of particular interest was to bring those individuals and

groups most impacted by crime into the project. Assessments of the CCP program pointed out that partnerships could be built and have a positive impact on the communities. A second important partnership program was Operation Ceasefire, which began in 1996. Like CCP, this project used a wide-ranging partnership of agencies to address gun violence in Boston. Using the efforts of all participants, Operation Ceasefire was able to reduce significantly the level of homicides by firearms. The Strategic Approaches to Community Safety Initiative (SACSI) took what was learned from CCP, Operation Ceasefire, and other partnerships and attempted to address the problem of violent crime in the target communities. This entry examines the development of SACSI and its impact on crime and the community.

Growth and Development

The SACSI project was initiated originally in 5 sites in 1998 and later expanded to 10 sites in 2000 to fight primarily violent personal crimes. The initial five sites included Indianapolis, Memphis, New Haven (Connecticut), Portland (Oregon), and Winston-Salem (North Carolina). The cities added in phase 2 were Albuquerque, Atlanta, Detroit, Rochester (New York), and St. Louis. The array of problems addressed in the various cities included homicide, gun violence, rape and sexual assault, and assaultive crimes by both adults and juveniles. All the projects were funded by the U.S. Justice Department through the National Institute of Justice.

The lead agency in the SACSI sites was the local U.S. Attorney's Office, which attempted to build a partnership that consisted mainly of other criminal justice agencies. Similar to Operation Ceasefire, SACSI included local, state, and federal law enforcement agencies; probation and parole offices; local, state, and federal attorneys; and social service agencies in the primary core of participants. Each of these agencies brought different strengths and abilities to the table. Of particular importance was the fact that each partnership included a local research team whose task was to analyze the problem in the community, participate in selecting the appropriate response, and evaluate the operations of the SACSI team. The primary framework for the work of the partnerships can be

described as following the SARA model—scanning the situation/problem and gathering information, analysis of the data, response by way of an intervention appropriate to the particular problem being addressed, and assessing the impact of the activities.

Evaluation

Most material available on the SACSI project is restricted to process evaluations which show that partnerships can be successfully established, although concerted effort is often needed to sustain them. Some outcome information has become available in recent years. In one evaluation, Scott Decker and his colleagues analyzed the ability of SACSI in St. Louis to reduce gun crime. They noted a significant reduction in gun crime, as well as a reduction in homicides after the initiation of the project. Similarly, an evaluation of SACSI in New Haven presented promising results. The New Haven project, TimeZup, involved a range of participants, including local law enforcement, the U.S. Attorney's office, the State Attorney's office, probation, parole, corrections, and social services. Eliot Hartstone and Dorinda Richetelli noted decreased levels of violent gun crimes, calls for service, and numbers of guns seized. Other positive results included the reduced fear of crime and increased confidence in the police.

The most recent evidence on the success of SACSI appears in a national evaluation that reports on project outcomes across all 10 target cities. Examining preprogram and postprogram police data, Jan Roehl and her colleagues find significant reductions in the crimes targeted in each location. For example, gun assaults were reduced by almost 60% in Indianapolis, homicide dropped by more than 40% in Portland, and forcible rape fell by 49% in Memphis. Interestingly, although the reductions started to appear before the initiation of the interventions, the positive results persist while crime data for all cities of 100,000-plus population in the United States show increasing homicide and violent crime.

The national evaluation attributes the success of SACSI to several key components. The first of these is the leadership provided by the U.S.

Attorney's Offices, which was instrumental at gaining the cooperation of key decision makers. Second was the ability of the program to assemble a strong partnership effectively that could work together effectively to identify the problem and arrive at interventions. An important third component was to build on prior partnerships. This allowed the programs to have a more immediate impact on the problems. The final aspect was to undertake meaningful research before, during, and after the implementation of interventions. The largest problem faced by the different SACSI partnerships was the lack of adequate funding to carry out their interventions fully.

STRUCTURAL CHOICE THEORY

The structural choice theory of victimization was first proposed by Terance Miethe and Robert Meier in 1990. It incorporates elements of the routine activities and opportunity perspectives on victimization, and it recognizes the importance of interaction between the variables typically included in empirical tests of their hypotheses. Structural choice theory also recognizes the importance of including multiple measures for variables typically associated with impacting the

risk of victimization, and it is a theory aimed at predicting the risk factors most conducive to victimization. This entry summarizes the elements that comprise structural choice theory, details some of the philosophical assumptions and predictions relative to the theory, and surveys some of the empirical research testing elements of the theory.

Assumptions and Predictions

In formulating the structural choice theory of victimization, Miethe and Meier take note of three assumptions made within the context of traditional victimization theories. First, per Lawrence Cohen and Marcus Felson's formulation of the routine activities perspective, most theories of victimization assume the convergence of a motivated offender and a suitable target in the absence of a capable guardian. Furthermore, it is implied that these occur within spatial and temporal proximity of one another.

Second, most existing theories assume that changes in the lifestyles of individuals have an impact on the likelihood of victimization. For example, in working-class neighborhoods (where residents ostensibly spend a considerable amount of their time away from home working), the absence of capable guardians is presumed to make their property more attractive to potentially motivated offenders. If those residents were to spend more time at home, then the implication is that their risk of property victimization at home would decrease. Another example provided by Miethe and Meier resides in neighborhoods that experience an increase in the number of single parent households, which presumably also impacts the likelihood of victimization through a decrease in the availability of capable guardians.

Third, most existing theories of victimization make assumptions philosophically related to rational choice theories of crime causation, namely, that potential offenders seek to maximize their profits while minimizing the attendant costs of criminal behavior. Rational choice theories are rooted in the concept of humans as rational utility maximizers, which in the spirit of John Locke and David Hume presume free will as the organizing principle of human

agency. Rational choice theories presume that offending individuals engage in a calculation, witting or otherwise, whereby offenders seek to increase pleasure while minimizing pain. It is presumed that by increasing the costs and penalties associated with criminal and delinquent behavior, potential offenders will forego their impending actions. Thus, rational choice theories hinge on the verisimilitude of the concept of deterrence, which has been the subject of considerable debate among scholars since the publication of Cesare Beccaria's *On Crimes and Punishments*.

Building on these assumptions taken from existing theories, the structural choice theory of victimization contains two propositions. Miethe and Meier consider each of them "a necessary condition" of predatory crime, which they contend is supported on the basis of prior literature specifying the importance of the convergence of these factors in space and time. First, "routine activity patterns and lifestyles in contemporary society create a criminal opportunity structure by enhancing the contact between potential victims and offenders" (p. 245). Second, "the subjective value of a target and its level of guardianship determine the choice of a particular crime victim" (p. 245). Thus, the structural choice theory of victimization includes both a structural component recognizing the importance of "proximity and exposure" to potential motivated offenders, and a choice component recognizing the importance of "target attractiveness" coupled with low levels of "capable guardianship."

These "necessary conditions" of predatory crime facilitate several predictions, which were articulated by Miethe and Meier in their original presentation of the theory. First, the absence of any necessary condition *must*, by definition, decrease rates of victimization when stated as above. The opposite is also true, in that if there are higher levels of those necessary conditions, then the risk of victimization *must* increase. Second, the researchers note that various combinations of the variables should highlight the impact their interaction has on victimization rates but recognize that the sophistication required in modeling those dynamics relative to the change in risk factors has not been addressed by any existing theory of victimization. Finally, one prediction made possible

by structural choice theory is that differences in levels of "attractiveness" and "guardianship" ("target selection factors") should be most pronounced by those experiencing relatively high levels of exposure to crime or who are already in close proximity to motivated offenders.

Empirical Research

According to Miethe and Meier, structural choice theory represents an advance over previous theories of victimization, in that it accounts for the interaction among variables typically included in models assessing the risk of victimization. Furthermore, they argue for including multiple measures for each of the traditionally relevant variables, which suggests that doing so would greater capture the multidimensional aspects of concepts like "capable guardianship" and "target attractiveness." Their first empirical test of structural choice theory revealed findings divergent from what would be expected in testing traditional theories of victimization. For example, the "target selection factors" ("guardianship" and "attractiveness" of target) were either insignificant or contrary to what one would expect from traditional theories predicting risk factors relative to victimization. The traditional variables of "proximity" and "exposure to motivated offenders" had the expected impact on victimization, but cumulative effects in combination with other variables were found to be insignificant, although the researcher question whether methodological decisions may have conditioned this result.

Miethe and David McDowell integrated specific elements from theories related to predicting the conditions conducive to crime with elements of victimization theories, which are generally concerned with how targets are selected by criminals, thus accounting for the impact of both criminal opportunity as well as the traditional social correlates of criminal behavior in explaining predatory crime. They suggested that including both levels of effects is important because the impact of structural conditions represented in the characteristics of neighborhoods may condition the impact of criminal opportunities. Furthermore, most sociological theories of crime causation tacitly suggest that structural

conditions do indeed impact the behavior of individuals.

Consequently, Miethe and McDowell examined the structural characteristics of neighborhoods in a way that is compatible with Clifford Shaw and Henry McKay's original formulation of social disorganization theory, which states that criminal behavior is associated with communities characterized as ethnically heterogeneous, populated with low-income residents, and possessing a high rate of residential mobility; these variables are ostensibly proxies for measuring the social capital of a community. They also included measures of criminal opportunities compatible with the routine activities perspective. Miethe and McDowell found that the socioeconomic status of a community did not significantly impact rates of property and violent victimization. Furthermore, when the community context was controlled, the opportunity-enhancing conditions of "living alone" and "having low income" did not affect victimization rates. Similarly, "target attractiveness" and "low guardianship" were only relevant in predicting victimization within middle- and upper-class neighborhoods. Their findings illustrate the relevance of combined models in predicting the likelihood of victimization in specific socially demarcated geographic areas.

Maria Velez assessed the impact of public social controls on victimization rates. "Public social controls" refer to the ability of a neighborhood to establish ties to local officials who can presumably assist in securing the resources necessary for controlling crime and disorder. It is presumed that disadvantaged communities suffer from a lack of such resources, which contributes to both higher rates of crime as well as higher victimization rates relative to more socioeconomically advantaged communities. Velez included controls for the variables included in previous tests of the routine activities perspective, neighborhood disorganization, and levels of disadvantage. Her findings indicate that public resources reduced victimization rates with respect to both household and personal offenses, and she found that the potential impact of these resources was more powerful in disadvantaged communities.

Bonnie Fisher and her colleagues examined the factors related to an increased risk of victimization

among students on college campuses. They hypothesized that several risk factors from the victimization literature may converge in the collegiate environment, which suggests that college students may have a greater likelihood of experiencing the consequences of criminal victimization. Those risk factors revolve around the fact that college campuses tend to be composed of young, unmarried students. Fisher and her colleagues also suggest that the sheer number of potential victims on college campuses may make them more attractive to motivated offenders, and the authors are consequently astonished that few studies of victimization have explored the collegiate dynamic. The authors found that the increased number of motivated offenders did not affect victimization rates in large college dormitories, reasoning that the residents may have had an increased level of awareness relative to their vulnerability of victimization. The researchers also found that victimization rates were higher for those living in exclusively male or mixed-gender dormitories (in comparison with those living in exclusively female dormitories or housed in off-campus locations); this finding is compatible with previous studies of risk factors related to victimization.

Laura Dugan and Robert Apel tested variations on structural choice theory in a way that represented a theoretical departure from traditional considerations of the routine activities perspective. Typically, the routine activities perspective is concerned with the spatial dynamics of crime in public places. However, Dugan and Apel note that not all crime is opportunistic in nature. Changes in routine activities (e.g., staying at home more often) have traditionally been hypothesized to decrease one's likelihood for victimization. However, those changes may also increase the likelihood that one becomes the subject of violence from intimates, which official data indicates is more common than stranger-on-stranger violence. Dugan and Apel hypothesize that "staying at home" may increase the likelihood of retaliation, particularly with respect to the crime of domestic violence; they term this condition the "irony of the routine activity model." In comparing domestic with stranger violence, they found that women were less sheltered by those traditional protective measures endemic to the routine

activities perspective. Furthermore, female victims were at higher risk for retaliation from intimates if they separated themselves spatially from their offender, contrary to what one would expect from traditional interpretations.

Future Directions

The structural choice theory of victimization formulated by Miethe and Meier represents an advance in that it recognizes the importance of potential interactions between variables typically included in other models of risk assessment. Future extrapolations of the theory will most likely increase its predictive power by specifying the factors that condition the impact of traditional lifestyle and opportunity variables.

SUBSTANCE ABUSE, PREVENTION OF

Substance abuse is a common correlate of criminal offending and victimization, yet there is no single, universal definition of substance abuse. The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* generally defines substance abuse as any substance use that is associated with persistent interpersonal, legal, occupational, and/or educational problems. It can also be used to refer to the use of substances in risky situations. The term *substance abuse* has been used broadly across research disciplines to cover behaviors such as substance use, misuse, abuse, and dependence.

Efforts to prevent substance abuse are concerned with eliminating the risk factors and enhancing the protective factors associated with drug use. The primary goal of substance abuse prevention is to intervene and halt the influence of risk factors while simultaneously enhancing the effects of protective factors against substance use and abuse. Prevention programming focuses on increasing knowledge about drugs and the dangers associated with their use, deterring or reducing use, delaying age of onset, encouraging the development of negative attitudes toward drug use, and fostering individuals' self-esteem and self-awareness. This latter focus serves the important task of addressing possible psychological correlates of drug abuse. Another key component of substance abuse prevention is aimed at peer-based programming, such as the development of refusal skills to combat peer pressure.

Risk Factors for Substance Abuse

Research has identified a variety of factors that put individuals at risk for substance use and abuse. These risk factors do not exist solely at the individual level but rather occur across multiple

domains. Much of this research has focused on youths, given the strong association between adolescent substance use and delinquency, and the negative impacts of these problem behaviors into adulthood. J. David Hawkins and his colleagues (1992) at the University of Washington succinctly summarized risk factors for both substance abuse and delinquency that exist across community, family, school, and individual levels. At the community level, risk factors for substance use and delinquency include the presence of attitudes favorable to drug use and crime, and the availability or perceived availability of drugs in the community. Another community characteristic, that is, increases in the transitions and mobility of community residents, can reduce the level of informal social control in a community, which may facilitate the tolerance of delinquent, substance-using subcultures. Also, communities with high population density and signs of physical deterioration have been shown to have higher rates of juvenile substance use and crime. Low levels of attachment to the community may also undermine informal social control, as can the community's level of economic deprivation.

At the school level, academic difficulty and low attachment and commitment to school may put youth at risk for substance abuse and delinquency. Youth who have positive attitudes toward school and their schoolwork are less likely to use substances. Within the family, risk factors for substance abuse and delinquency include a history of problem behaviors among family members, family management problems, poor parental monitoring, and high levels of family conflict. Parental behaviors that may serve as risk factors for youth include severe, inadequate, or inconsistent discipline, as well as parental substance use, criminal behavior, and/or parental attitudes favorable to drug use and crime. Studies frequently find that youth whose parents engage in substance use or crime are more likely to use alcohol, tobacco, or other drugs.

Individual-level risk factors include personality characteristics such as antisocial behavior, feelings of alienation, aggression, and rebelliousness. Association with peers who themselves abuse substances and/or engage in other criminal behavior is a prominent risk factor for these similar behaviors in youths. Even associating with peers who have

attitudes favorable to drug use and crime, regardless of whether or not they use substances or commit delinquent acts, puts youth at risk for engaging in substance abuse and delinquency. Substance use by romantic partners is another risk factor for individuals' substance use. Early initiation of drug use is a risk factor for continued substance abuse problems that has also been associated with delinquent behavior.

Protective Factors for Substance Abuse

Much of the scholarship on substance abuse focuses on risk factors; however, given that the primary goals of prevention programming concern reducing risk factors while simultaneously enhancing protective factors, it is important to review some of the characteristics and contexts that deter individuals from abusing substances. Protective factors can lessen the impact of risk factors on the likelihood of using drugs and represent more than merely the opposite or absence of risk factors. Protective factors are often understood as interacting with risk factors. For example, a strong attachment to parents may lessen the effect of associating with drug-using peers on one's own likelihood of substance use. Supportive, affectionate families are often cited as protective against substance use and delinquency. Parents who provide opportunities and rewards for their children to engage in positive, prosocial behavior have children who are less likely to engage in substance use and delinquent activities. This can also serve to strengthen negative attitudes toward substance use. Attachment to community members or school may buffer the effects of family conflict. Social bonding to parents, school, and community are particularly important protective factors that may operate alone or in conjunction to reduce youths' risk of substance use and abuse, as well as delinquency.

The Importance of Substance Abuse Prevention

Research frequently highlights the links between substance abuse and criminal offending and victimization, emphasizing the need for substance abuse prevention in crime-reducing efforts. In terms of the association between substance abuse

and victimization, several nationally representative surveys have found associations between childhood physical/sexual victimization and substance abuse problems later in life. The direction of the relationship between victimization and substance abuse is unclear and possibly even bidirectional. It has been suggested that violent victimization influences substance abuse because victimization leads to psychological distress or posttraumatic stress disorder (PTSD), which facilitates substance use and abuse as a coping mechanism. Also, victimization leads to feelings of guilt, shame, or isolation; stigmatization; and feelings of belonging to some disconnected “other,” which may lead to identification with alienated, deviant groups and individuals, who may provide opportunities for substance use and normative definitions favorable to drug use and abuse. Alternatively, substance use and abuse may be associated with violence through impaired decision making by both victims and offenders. Individuals who are under the influence of substances may be unable to perceive adequately risky or dangerous situations and potential offenders. Intoxicated individuals are more vulnerable targets. Potential offenders who abuse drugs may have impaired perception of victims’ resistance cues. Substance use often occurs in contexts or environments that may condone or encourage other types of criminal behavior.

Types of Substance Abuse Prevention Programs

Many past substance abuse prevention efforts have focused on reducing risk factors in one or more specific areas. Early methods concentrated on targeting supply and enhancing law enforcement to deter use. For example, there have been various prohibitions on the sale of alcohol, including age restrictions, restrictions on hours available for purchase, and restrictions on the amount purchased at a time. Law enforcement efforts were increased to combat drug offenses, and criminal justice responses became harsher; however, none of these methods seemed to impact significantly the supply and demand of substances.

Another approach to substance abuse prevention involves modifying public opinion about substance use to enhance the social disapproval of such behavior. Various antidrug coalitions, media

campaigns, and policy changes have been implemented, all with varying degrees of success. Similarly, classroom-based programs that teach skills for better resisting the pressures of peer substance use have become popular, with evidence suggesting success at reducing drug use. Because of the spike in delinquent activity occurring during the hours at the end of the school day, many prevention programs have been implemented as after-school programs that provide antidrug messages, education and social skills development, as well as prosocial recreational and leisure activities, such as the Drug Abuse Resistance Education (D.A.R.E.) or the Boys & Girls Club.

More recently, primary prevention refers to “universal” programs designed for populations who have not yet begun engaging in substance use. This type of programming focuses on the prevention of substance abuse prior to the initiation of any substance use. Secondary and tertiary prevention represents “targeted” programs focused on intervention efforts to reduce and eliminate substance use among individuals who are already using. These types of prevention programs adhere to a risk-reduction or harm-reduction model that is more applicable to individuals who have already used substances.

As noted above, risk factors for substance abuse and crime exist across multiple levels, including the community, school, family, and individual. Therefore, prevention programs can be implemented at any one of these levels or across more than one level. For example, school- or individual-based prevention programs may provide education, information, and awareness about drugs and their associated effects, peer pressure resistance skills, and decision-making skills. Family-based prevention strategies can focus on enhancing family relationships and parenting skills. Community-level prevention programming may address the provision of opportunities for youth involvement in positive, community activities, and youth interaction with supportive community members who can also act as mentors or role models. A review of specific prevention programs is beyond the scope of this entry; however, program evaluations are presented and discussed in numerous primary papers, meta-analyses, and review articles in psychology, sociology, and public health journals.

At-Risk Populations and Contexts for Substance Abuse Prevention

Although most prevention researchers focus on adolescents, colleges and universities are a context vulnerable to both substance abuse and violent victimization, and these examples represent a setting where substance abuse prevention programming is needed. The abuse of alcohol and other drugs has been associated with sexual victimization, particularly for female college students. Evidence also suggests a reciprocal relationship, where substance abuse is associated with victimization, which is then associated with subsequent substance abuse.

Studies suggest that university women are at greater risk of sexual assault than women of a comparable age in the general population, likely because of the close daily interaction between men and women in a range of social situations as well as frequent exposure to alcohol and other drugs. This relationship between substance abuse and sexual assault has been illustrated in studies showing high levels of alcohol and other drug use before the incident by both victims and perpetrators, and by studies that demonstrate substance abuse occurring as a coping mechanism after the victimization. Substance use can incapacitate victims, make it difficult for them to consent to or refuse sexual activity, or lead them to take risks they might otherwise avoid. Substance abuse may decrease a perpetrator's awareness of his behavior, lead to the misinterpretation of resistance cues, or diminish the victim's ability to prevent an assault. Substance use by both victims and perpetrators has been associated with increased severity of injury.

Prevention programming is particularly important in this context because substance use at the time of the incident may inhibit victims' willingness to report their victimization, either because victims blame themselves or because their use of substances has impaired their ability to recall sufficiently various details of the incident. Because many sexual assaults experienced by university women occur in conjunction with the use of alcohol or other drugs, the risks of substance abuse must be addressed in prevention messages presented to university students, particularly the risk of drinking to excess. Certain characteristics of college culture may promote substance abuse. For

example, there are increased opportunities to attend parties where alcohol is served and other substances are available. The proximities of bars to campus and fraternity or sorority residences have also been linked with increased substance use. For many students, college offers an environment notorious for encouraging excessive drinking and experimenting with drugs. Many students may be unaware of the effects of mixing drugs and alcohol, and they may be unfamiliar with the point at which their cognitive ability is so impaired that they cannot protect themselves. Substance abuse and early initiation of substance use puts one at risk for violent victimization and a variety of other negative health consequences. Prevention programming is needed across multiple domains (individual, family, school, and community) and across various target populations (adolescents, university students, and adults).

Principles of Substance Abuse Prevention Programming

The National Institute on Drug Abuse has summarized key general principles for effective substance abuse prevention programs. The primary goal for prevention programming is to inhibit risk factors while enhancing protective factors. It is also necessary that prevention efforts address all types of drug use and abuse. This is particularly important given evidence indicating that alcohol abuse puts one at risk for the subsequent abuse of other licit and illicit substances. Given the multiple levels of risk factors, prevention programming should not neglect issues of drug abuse in the community. Programs must also be tailored to the specific needs of different at-risk populations, such as disadvantaged youth, college and university students, and racial/ethnic/sexual minorities. Effective prevention programs are theoretically driven, provide sufficient dosage; provide opportunities for positive, prosocial relationships; and have well-trained staff.

Successful prevention planning and evaluation involves the identification of specific goals and objectives, a thorough review of previous evaluation research, a conceptual framework of how the program will operate, a plan for the collection of program evaluation data, and the ability to provide feedback on the program's effectiveness.

In their report on prevention efforts to combat substance use on campuses, the National Institute on Alcohol Abuse and Alcoholism reviewed specific prevention strategies for colleges and universities. The specific goal of university substance abuse prevention programs may be to eliminate student substance use, reduce excessive consumption of substances, deter substance use-related problem behaviors, and so on. A “needs assessment” can be a useful tool for program planners to solidify their specific goals.

Prevention programs to reduce substance abuse by college students can be implemented at multiple levels, such as the individual, group, college, or community. At the individual level, alcohol and other substance awareness programs can be used to instill negative attitudes about substance abuse and provide students with information about various problem behaviors associated with substance abuse. Workshops, retreats, and other training activities may connect better with students than do lectures. Group-level prevention programs focus on impacting peer-to-peer communication about substance abuse norms in an effort to reduce consumption. This type of prevention strategy is particularly useful for highly interactive groups, such as fraternity and sorority members, or members of athletic teams. Providing students with accurate information about the substance using behavior of their peers can help them adjust their behavioral expectations accordingly, and it can reduce perceived social pressures to drink heavily and abuse substances. At the college or university level, institutions can promote activities that do not involve drugs or alcohol, limit alcohol availability and restrict the marketing and promotion of alcohol, and develop and strictly enforce campus antidrug policies. Community and campus coalitions can work together to reduce students’ alcohol use by reducing the number of alcohol outlets near campus and limiting the available hours of alcohol sales. Also, colleges and local law enforcement agencies can collaborate to establish driving under the influence stops on weekends.

Challenges and Implications for Studying Substance Abuse Prevention and Crime

No single prevention strategy or organization framework exists, and many evaluations of prevention

programs have been plagued with various methodological limitations, such as participant dropout (“attrition”) and problems with program implementation fidelity. As such, it is difficult to identify effective “evidence-based” prevention programs, and some widely disseminated prevention programs have received conflicting evaluation findings. Despite these methodological challenges, substance abuse prevention remains an important area in the study of victimization and crime. Given the strong correlation between substance abuse and crime, it is important to link prevention, intervention, and treatment efforts. Substance abuse prevention programming should consider the inclusion of techniques focused on the prevention of subsequent victimization. Previous prevention efforts have been focused on risk reduction; however, it is necessary also to enhance protective factors to achieve effective programming.

SUBSTANCE ABUSE, TREATMENT OF

Substance abuse involves the overuse of, dependency on, and/or addiction to nonfood items, natural or synthetic, that changes an individual's body and/or mind because of their chemical composition. In general, the drugs of alcohol, marijuana, cocaine, heroin, and methamphetamine tend to be the most abused substances that often require regimented treatment approaches for successful cessation. Although surveys have demonstrated that substance abuse has been decreasing since the early 2000s in the United States, it still remains a problematic behavior that affects youth, families, employers, co-workers, schools, and communities. Prevention and intervention programs have attempted to address the issue of substance abuse using a variety of methods across several ecological levels, such as the individual, the family, the school, and the community.

Whereas some programs, such as Drug Abuse Resistance Education (D.A.R.E.) and other community antidrug programs, operate mostly to prevent initial drug use, these are not the focus of this entry. Rather, the examples that follow highlight the commonly used approaches for treating persons already addicted to drugs. Before discussing these interventions, however, a review of principles observed in more than 20 years of research as to what is effective in drug addiction treatment is noted.

Effective Drug Addiction Treatment

In 1999, the National Institute of Drug Abuse reported on 13 principles found to characterize successful treatment for drug addiction. These principles are still hailed today as core qualities that should be recognized and followed when treating addicts. First, one treatment approach will not work for all addicts. Second, treatment must be immediately available and accessible by users. Third, treatment should extend beyond the drug use and include assistance with related medical, mental, and vocational problems. Fourth, flexibility in treatment is important, as individuals' needs will likely change over the course of the program. Fifth, adequate time in treatment is vital to its success, and tactics should be employed to prevent individuals from leaving before completion. Sixth, counseling and behavioral therapies are fundamental to successful outcomes. Seventh, the use of medications may be necessary for some addicts. Eighth, many addicts often have co-occurring mental disorders and should be assessed and treated for both at the same time. Ninth, detoxification (i.e., managing withdrawal symptoms with the use of chemicals) without additional treatment elements is not sufficient for long-term substance cessation. Tenth, individuals do not have to attend treatment voluntarily to observe success. Eleventh, monitoring drug use during the course of treatment is important as it provides the client with a tool to withstand cravings and allows for adjustments in treatment should drug use be detected. Twelfth, assessments for hepatitis viruses, HIV/AIDS, and tuberculosis, along with other diseases, should be conducted. Finally, several attempts at treatment may be needed to achieve success.

Types of Treatment

Methadone Maintenance

Methadone maintenance programs have been used since the mid-1960s in the United States to treat heroin addiction. Heroin addicts are given methadone to detoxify from heroin so they do not have to experience fully the symptoms of withdrawal, which have been likened to having a serious bout of the flu. The premise for the detoxification component, which is the cornerstone of methadone maintenance, is that once the physiological dependency to heroin has been lessened, counseling and other therapeutic strategies have a better chance of working.

The drug methadone was developed during World War II in Germany when the painkiller morphine was no longer accessible. Heroin and morphine, like methadone, are classified as a narcotic, which means they have analgesic and sedative effects. Typically, one narcotic can be substituted for one another and similar effects, although varying in intensity, can be experienced by the user. Methadone can be just as addictive as heroin, but its impact is not as impressive because it is a longer acting narcotic compared with heroin. The effects of one dose of heroin last between 2 and 3 hours, whereas one dose of methadone affects the user up to 24 hours.

Methadone is orally administered to addicts under inpatient care and then clients are eventually maintained on an outpatient basis. At first, low doses of methadone are administered to curb the heroin withdrawal symptoms. Dosages are then increased incrementally to the point where the user no longer experiences the euphoric or sedative effects of the methadone. Once patients' cravings are alleviated and tolerance develops, they can leave the facility and retrieve their maintenance doses on a daily basis.

Research evidence is mixed on the effectiveness for methadone maintenance programs. Some studies indicate that many methadone maintenance patients use other drugs during and after treatment, such as cocaine and marijuana, as well as heroin. Other studies have found, however, that for some addicts, treatment in a methadone maintenance program can lead to favorable outcomes such as for those clients (1) who are motivated to abstain from heroin, (2) who believe methadone

will work, (3) who are looking for a chemical cure to their addiction, and (4) who have aggressive tendencies and used heroin to control their emotions whereby methadone could readily act as an appropriate substitute.

Methadone is not the only drug that has been used to treat narcotics addicts. Other drugs that have been approved for use include levo-alpha-acetyl-methadol (LAAM), buprenorphine, and naltrexone. LAAM has been approved by the Federal Drug Administration (FDA) to use in place of methadone since 1993, mainly because LAAM's effects on the patient lasts longer, up to 72 hours, and it metabolizes through the body more slowly thereby not producing that quick high narcotics addicts seek. Buprenorphine is the newest of the heroin substitutes used for treatment, and it is one of the only therapy drugs that can be prescribed by a doctor as opposed to being distributed by a clinic like methadone and LAAM. Like its counterparts, buprenorphine assists in cessation by attenuating withdrawal symptoms and easing cravings. Its effects last between 24 and 60 hours. Naltrexone has been approved by the FDA for heroin dependency treatment since the mid-1980s, and within the past several years, it was approved to treat alcoholism as well. It works by blocking the receptors in the brain that deliver the euphoria experienced when individuals consume alcohol and narcotics in a similar manner to that of methadone and LAAM. Overall, the results from various evaluation studies demonstrate that maintenance therapy with any of these medications can be highly effective when administered in the appropriate setting and dosage, and when patients are committed to reducing their dependency on addictive substances.

Therapeutic Communities

Set in residential facilities, therapeutic communities (TCs) are residential programs designed to rehabilitate substance abusers. They have been in existence since the 1960s. TCs are different from other types of drug treatments in their use of the total community principle. This principle relies on the idea that both staff and patients are key agents in achieving abstinence from drugs. The staff are typically ex-addicts who have already graduated from a TC program, although some TCs employ

professionals to work with the residents. The main purpose of the TC approach is to bolster ego functioning by helping addicts cope with the negative behavioral and cognitive patterns that led them to their drug use such as alienation and low self-esteem.

In most TCs, patients progress through a series of stages that reward additional personal and social freedoms and privileges over the course of treatment. Individual and group counseling are used along with approaches that assist patients in learning prosocial norms and improving social skills. There is heavy reliance on the influence of peers and the idea of community, which is often likened to a surrogate family. Vocational and educational training are also offered to residents of TCs to assist them in reintegrating into society after release. The time spent in the TC is dependent on each patient's successful completion of each stage of the hierarchical model. Most patients spend between 6 and 12 months in the TC.

According to many studies, TCs are effective for program graduates. However, it is important to note that TCs might be designed to succeed not because of the programmatic aspects of the treatment but because of the screening process used for selecting patients. In addition, graduating from a TC does not necessarily imply that graduates remain or are drug free; rather, graduating means that patients successfully progressed through each stage of the process with full freedom and privileges being a component of the final step. Studies find that addicts who will do well post-TC are those who are mentally healthy, have few to no ties with other offenders, and have solid employment skills.

Although TCs are commonly located in communities, several states have had TC programs in operation in some of their prisons. These TCs go by the name of "Stay 'n Out." Inmates in the Stay 'n Out programs reside separately from the general prison population. Graduates of community TCs and ex-inmates staff the program as role models for rehabilitation. Stay 'n Out programs generally last between 6 and 9 months. Once released from prison, Stay 'n Out graduates are encouraged to join a TC based in their local community. Evaluation studies of the Stay 'n Out program have found reductions in recidivism for program graduates.

Outpatient Drug-Free Treatment Programs

Components of drug-free outpatient treatment programs can be varied and can include any of the therapeutic approaches described in this entry aside from the use of medication like methadone to reduce substance dependency. The basis for many of these types of programs is founded on the mental health perspective. Individual and group counseling, family therapy, referral to other social services, and relapse prevention are commonly used. It is difficult to determine the overall efficacy of outpatient programs of this nature because each program can differ markedly from another. For example, some programs may operate in drop-in centers, whereas others may be more structured with weekly counseling sessions. Notwithstanding the limitations, evidence does seem to show that these treatment programs are at least partially effective in decreasing substance use and crime.

Psychological Treatments

Psychological treatments are common elements of many drug treatment programs. Psychological approaches are as varied as the field of psychology itself ranging from practices based on psychoanalysis to behaviorism. In general, psychological treatments aim to change the reasons, motivations, and triggers that are believed to drive individuals to use drugs and become/remain addicted. Studies have found support for many of these strategies, and the cognitive-behavioral therapies are among the most efficacious. This section provides an introduction to some of the most commonly used psychological treatments for drug addiction.

Cognitive-Behavioral Therapy

Treatments based on cognitive-behavioral approaches assert that behavior is learned, both prosocial and antisocial. Problematic behaviors, like drug abuse, are targeted by teaching the addict to understand his or her patterns of thinking that reinforce continued substance use. Therapists assist patients by helping them determine the positive and negative aspects of their drug use. Addicts also acquire the skills to identify the variables that drive them to use drugs and then to develop coping strategies to combat these triggers by avoiding high-risk places, people, and situations. For example, if a

patient is influenced by drug using peers, he or she is taught the skills to counteract the pressure to use drugs by not associating with these people.

Supportive-Expressive Psychotherapy

This form of psychotherapy relies on techniques that addicts can use to feel more comfortable during treatment (i.e., the supportive component) and strategies designed to assist in working through interpersonal problems with significant others that may have contributed to continued drug usage and addiction (i.e., the expressive component). Supportive-expressive psychotherapy was developed originally to treat depression and anxiety disorders, but it has since been modified to treat heroin and cocaine abuse. Emphasis is placed on helping the addict understand the role drugs play in relation to adverse life experiences and feelings. Alternatives to drug use are explored, and the use of these options is encouraged when faced with these problems and negative emotions. Therapists facilitate the sessions by helping the user identify themes related to the addiction such that when faced with similar situations, the patient has other means besides drugs to cope.

Motivational Enhancement Therapy

Motivational enhancement therapy centers on the client in a counseling relationship with a therapist who encourages an otherwise ambivalent addict to participate in drug treatment and abstain from using drugs. Studies demonstrated that it is effective for individuals dependent on alcohol and marijuana. Strategies used in this type of therapy are designed to inspire users to look inward for behavioral change. Assessments are conducted to determine what principles and cessation methods will encourage the client to become self-motivated and subsequently drug free. Relapse prevention techniques are also identified so that high-risk situations can be avoided. Change in drug using behaviors is regularly monitored by the therapist such that continued commitment to working toward being and/or remaining drug free is embraced by the client.

Behavioral Therapy

Behavioral therapies are mostly used with adolescent drug users rather than adults, but some

programs have been adapted to work with adult addicts as well. For changes in behavior to occur, desired behaviors, in this case, not using drugs, are demonstrated by role play and modeling. Individuals are rewarded when they can show positive progress toward cessation. Typically, urine samples are taken to determine whether clients are using drugs. Program participants are given various assignments to help them achieve several goals. For example, individuals who spend more time socializing in drug-free activities would be rewarded with praise and/or privileges, such as a special food treat. Similar to the cognitive-behavioral therapy, addicts are also taught to identify and then alter their thoughts, emotions, and circumstances that would normally have led them to use drugs had these clients not been in a behavioral therapy program. Family members are encouraged to participate in the treatment to assist in identifying the triggers that could lead to relapse. Behavioral therapies, like most other treatment approaches, can be delivered on an inpatient or outpatient basis.

Multisystemic Therapy

Multisystemic therapy is designed to treat the substance abuse problems of antisocial children and adolescents by addressing the variables associated with serious delinquency and crime. Adolescent, school, family, peer, and neighborhood factors are targeted. For example, individual and peer attitudes toward drug use, problems in school, criminal subcultures, ineffective parenting, and family conflict issues are reflective of the issues impacted by this form of family-based therapy. By focusing on the factors that influenced the problem behaviors, which are tailored to each client, youth will learn to turn away from using drugs and focus on more prosocial activities. Multisystemic therapy is typically applied outside of a secure residential facility. Some studies demonstrate that this treatment is effective in decreasing dependency on drugs, improving family relations, and reducing recidivism.

Individual Counseling

Counseling is the hallmark of most treatments, drug or otherwise. It involves lengthy discussions between a therapist and patient one to two times per week either in a residential setting or on an

outpatient basis. Counseling can encompass any of the psychological treatment approaches available as well as other forms of treatment such as methadone maintenance. The main goal is to encourage the addict to stop using drugs. Methods used are tailored to the individual and may involve employment skills training, family therapy, participation in a 12-step program, and mental and/or physical health treatment. Similar to other approaches, coping strategies are taught to assist the addict in identifying the triggers that led to past, or can lead to, future drug use. Thus, relapse prevention techniques are important in eliciting a drug-free lifestyle.

Self-Help Programs

Self-help programs are designed for individuals not seeking more formal treatment for addiction like those described above. Most self-help programs are best known as “12-step programs” whereby participants attend meetings on a regular basis while moving through a series of objectives that will assist them in achieving sobriety. In sum, the 12 steps emphasize that addicts become cognizant and verbalize their powerlessness over drugs, confess their transgressions against others and make efforts to rectify them, and requires a spiritual component that seeks the assistance of a higher power to lead addicts to sobriety. Alcoholics Anonymous is probably the most well-known and popular of self-help programs. Other programs for substance abusers include Narcotics Anonymous, Cocaine Anonymous, and Drugs Anonymous. The techniques used, along with working through the 12 steps, include giving and receiving support from peers in the program and communicating stories of addiction and problems in a group setting.

Studies have reported observing reductions in drug and alcohol use by 12-step program participants, particularly for those individuals who attend meetings on at least a weekly basis. These types of programs are generally self-selected as opposed to court-mandated for many participants. However, for some offenders, conditions of probation or parole might include participation in a 12-step program. Increasingly, self-help programs are being encouraged for individuals completing other forms of treatment as a method of relapse prevention.

SUBSTANCE USE AND VICTIMIZATION

Victimization as the result of substance use is defined as the consistent and persistent use of mind/behavior-altering substances both legal and illegal that subsequently lead to the criminal abuse of another. The relationship between substance use and victimization is a major social concern in the United States and other countries around the

globe. Approximately, 50% of victimizations involve persons who were under the influence of a mind-altering substance. With the influx of substance-related victimizations associated with adolescent, college student, and adult abuses researchers have begun to study this relationship more intensely. Although national reports of victimizations have decreased, substance-related victimizations continue to be a social concern. Overwhelmingly, young people comprise the majority population of victims as the result of alcohol and substance use. Victimization of youth most typically involve physical aggression and predatory victimizations, that is, stalking, rape, and unwanted sexual contacts.

Historical Perspective

The recognition of victimization as a concept to be reckoned with is fairly new. This newfound status, victimization, typically referred to women/spouses who were abused by their husbands. Prior to the mid 1900s, no social policies were in place to protect victims. In addition, spousal/intimate partner victimizations were largely ignored by law officials who neglected these matters, citing that these victimizations were personal matters of family and not law. Consistent with historical data, however, males are more likely to be victimized than their female counterparts, with the exception of sexual victimizations, particularly substance-related victimizations. Several historical trends have changed over time, including the definition of "substances." Early on, substance-use-related victimization was largely focused in the area of alcohol as an explanation of spousal/intimate partner abuse. Recent research, however, has shown that different substances, including alcohol and an assortment of other drugs (marijuana, opiates, methamphetamine, etc.), impact victimization across diverse groups, such as adolescents, young adults, most typically college students, and the traditional married/intimate partner victimizations.

Theory and Social Policy

Routine Activities Theory

As the result of increased victimizations, Lawrence Cohen and Marcus Felson's routine

activities theory was proposed as a solution to assist victims of crime. Routine activities theory hypothesizes that victimizations were the direct result of a person's regular routines, their ability to be targeted by a willing participant, and the lack of capable supervision (social control mechanism) to prevent the victimization from occurring. In their attempt to address victimizations and not crime, these researchers provided valuable guidelines to decrease likelihood of victimization. Regarding substance use and victimization, routine activity theory explains that potential victims be aware of places frequented (bars and clubs).

Victim-Assistance Programs and Restorative Justice

To assist victims of crime including substance-use-related victimizations, victim-assistance programs were created in the latter part of the 20th century. The main purpose of victim-assistance programs was to provide victims with resources (monetary compensation, counseling, etc.) that would assist them in their recovery and return to an otherwise normal quality of life as a productive citizen in society. Likewise, the restorative justice ideology has impacted victimized persons and is heavily weighted in the belief that because most crime victimizations occur between parties known to the victim, restoring relationships is crucial in controlling for a safer society after the offender's release from jail/prison. The hope is that restored relationships would decrease likelihood of revictimization, as the result of increased ownership of responsibility on behalf of the offender and forgiveness on behalf of the victim.

Victim Roles

The impact of substance use and victimization on societies has proven to comprise a limitless danger. Specifically, the relationship between substance use and sexual victimizations on college campuses around the nation are disproportionately represented in the literature. Similar to expansions beyond alcohol-related substances, victimization roles and types have also become much more diverse. Compared with early accounts of sexual victimizations where females were largely victimized by their male counterparts, more recent

accounts of victimizations reveal that the substance use and victimization relationship has expanded from the traditional unidirectional relationship of male-female victimization to a bidirectional and even multidirectional trend reflecting female-male, male-male, and female-female substance-related victimizations.

Sociologists and criminologists alike have become increasingly concerned with the ever-changing roles of victims. Research has linked the relationship between substance use and victimization to childhood trauma and suicidal behavior. Victimization roles have also expanded to include victims of HIV/AIDS-related unprotected sex while under the influence of alcohol and drugs. Substance use and victimization is a major societal concern that affects every facet of civilized and uncivilized cultures around the world. And although this relationship is not a new phenomenon, substance use and victimization has expanded and now seemingly affects every subset of our society including the young. Alcohol and drugs continues to account for significant variations across victimized populations.

SUBSTANCE USE AND VIOLENCE AGAINST WOMEN

Violence against women (VAW), which encompasses acts of physical, sexual, or psychological aggression perpetrated against females of any age, affects approximately one in five women during their lifetime and is recognized as a major public health problem worldwide. Child sexual abuse and intimate partner violence are among the most common forms of VAW. Extant literature links VAW with several adverse health problems, with substance use being one of the most common. This entry provides a brief overview of the relationships between VAW and substance use, as well as discusses the importance of prevention and intervention efforts addressing the interrelationships between substance use and violence to reduce VAW effectively and prevent related substance use problems.

Relationships Between VAW and Substance Use

Alcohol and drug use among victims and perpetrators has been linked to various forms of VAW, including domestic violence and sexual assault. Substance use has been indicated as both a risk factor for and consequence of VAW. Several pathways linking violence to substance use have been proposed with empirical support for each. The physiologic effects and expectancies of alcohol and drugs may increase aggression among both men and women and may increase risk for VAW. Empirical findings supporting this theory include evidence showing men were more likely to be

physically aggressive toward their female partners on days they consumed alcohol. Many behaviors for obtaining drugs (e.g., buying and selling) and environments for consuming substances (e.g., fraternity parties) have also been thought to place women at risk for VAW. For example, studies suggest that alcohol consumption at fraternities may be linked to greater risk for sexual victimization among women.

Substance use has also been indicated as a consequence of VAW. A substantial amount of literature suggests that women with histories of interpersonal violence may turn to alcohol and drugs to avoid the adverse feelings associated with violence victimization. For example, women with histories of childhood abuse, including childhood sexual or physical abuse, have been found to be more likely to have substance use problems compared with the general public, and women with substance use problems have been found to be more likely to have had histories of childhood abuse than those without substance use problems. Furthermore, evidence suggests that the relationships between VAW, including childhood trauma and substance use/problems may be mediated by psychological problems, which include posttraumatic stress. This body of work, along with other studies, has provided evidence for tension reduction theory and the self-medication hypothesis, which posit that women may turn to drugs and alcohol to cope with the negative affective states associated with VAW, including depression, anxiety, and posttraumatic stress.

Intervention

Although substance use is an etiological risk factor for VAW and an associated consequence of VAW, interventions for victims and perpetrators of VAW have traditionally failed to address the combined relationship between violence and substance use. For example, violence perpetration and victimization has typically been a neglected part of substance use treatment. Similarly, substance use has tended to be a neglected part of treatment for victims or perpetrators of VAW. For example, several treatment interventions for adult female survivors of child sexual abuse have excluded women with substance-use problems. Batterer treatment interventions have also largely failed to provide integrated treatment

for substance use and violence, even though evidence suggests that doing so may be more effective in reducing domestic violence. Although there have been more recent efforts to provide integrated substance-use treatment to victims and perpetrators of violence, more work is needed to make this type of treatment intervention more common.

In part, the independent treatment interventions for substance use and VAW, including psychological problems associated with VAW, were fueled by debate in the field about the temporal order for which to treat adverse consequences associated with VAW (e.g., posttraumatic stress) and substance use. Some have argued that addressing addiction should be a priority before addressing issues pertaining to violence (e.g., posttraumatic stress), whereas others have argued that treating the potential underlying triggers to substance use, such as the impact of interpersonal violence in women's lives, must precede interventions to reduce substance use.

Prevention

Prevention interventions aim to reduce adverse behaviors, such as substance use and violence, before treatment is needed. The three main types of prevention interventions are universal, selective, and indicated. These terms have replaced the previously used prevention intervention terms primary, secondary, and tertiary prevention. Universal prevention strategies are those that target the entire population with the aim of providing information to the entire population to reduce engagement in an adverse behavior (i.e., substance or violence perpetration). Public service announcements are one type of universal intervention that raises awareness about substance use problems or domestic violence in effort to reduce these problems. Selective interventions are prevention efforts that target persons at risk for substance use and VAW, whereas indicated interventions are prevention efforts aimed to prevent the progression of engaging in an adverse behavior, such as substance use, from becoming clinical (i.e., meeting criteria for substance dependence). Traditional prevention efforts have tended also to address VAW and substance use independently. Given the growing literature showing the interconnectedness between these two behaviors for both victims and perpetrators of

VAW, more integrated prevention efforts focusing on the intersect of substance use and violence are also warranted to reduce VAW and substance use effectively, which is a risk factor for VAW.

SUPPLEMENTARY HOMICIDE REPORT (SHR)

Homicide victimization is significantly lower than any other type of violence. Yet this extreme form of violence has significant impacts—on families and communities, fear of crime, resource allocation, and so forth. Crime-prevention strategies require information about the prevalence, distribution, and etiology of homicide victimization and offending across various sorts of places and over time. Such information is available from the Supplementary Homicide Report (SHR), which is a widely used data source on murder, non-negligent manslaughter, and justifiable homicides in the United States.

Description

The SHR data have been collected and compiled by the Federal Bureau of Investigation (FBI) since 1976 as part of the Uniform Crime Reporting (UCR) Program. Law enforcement agencies reporting a homicide offense or arrest on the basic UCR Program Return A form are to submit a supplementary homicide report with more detailed information on each incident. Most law enforcement agencies around the country (90%-plus) voluntarily submit monthly SHR data directly to the FBI or via their state UCR Program. Recently, however, fewer agencies are submitting homicide data.

The SHR data set is unique because it is the only national program that collects information describing the homicide offender, victim, relationship between them, time of incident, location of offense, type of weapon, and situational elements, such as the precipitating circumstance. The SHR individual-level data are flexible and allow researchers to analyze victims, offenders, or incidents. The data also may be aggregated to compare homicide rates across territories (e.g., counties, both rural and urban), time periods, and different age/race/sex groups.
